When the author and his associates in 1954 reported 4 cases of a familial cerebrodegenerative disease, characterized by the excretion of urine with a maple sirup-like odor, they were unable to determine the nature of the substance responsible for the urinary odor. Since then, 6 additional cases of the syndrome, occurring in 3 unrelated families, have been brought to their attention. The disease in all these children was characterized by early onset of spasticity and myoclonic seizures with rapid progression to decerebrate rigidity. Death ensued between 15 days and 20 months of age. The author obtained urine samples excreted by one of these children during the last months of life. These urine samples contained large amounts of alpha-ketoisocaproic acid, the keto analogue of leucine, together with smaller quantities of the keto acids of valine (alpha-ketoisovaleric acid), and isoleucine (alpha-keto-beta-methyl-n-valeric acid). These substances may indirectly be responsible for the unusual urinary odor.

The presence of large quantities of keto acids in the urine represents a distinctly abnormal phenomenon. The presence of several keto acids in association with a severe cerebrodegenerative disease suggests that these 2 findings are causally related and recalls the findings in phenylketonuria. In the latter condition, the urine has a peculiar "mousy" odor, probably caused by the presence of phenylacetic acid. The author discusses several possibilities that may account for the accumulation of alpha-keto acids in the urine. He believes that a failure of the transamination reaction or a failure in the excretion or utilization of amino acids can be excluded, but that an impairment of the degradative metabolism of the branched-chain amino acids may be an important cause of the cerebral degeneration in maple sirup disease.

DERMATOLOGY

Relaxin (Releasin) Therapy in Diffuse Progressive Scleroderma: A Preliminary Report. J. A. Evans. A. M. A. Arch. Dermat. 79:150-158 (Feb.) 1959 [Chicago].

The author reports on 9 women and 2 men, between the ages of 19 and 55 years, with scleroderma who had undergone sympathectomy and were treated with relaxin (Releasin), a polypeptide-like hormone obtained from the ovaries of pregnant sows. Scleroderma was especially severe in the hands and face. All but one patient had Reynaud's phenomenon. Nine of the 11 patients had esophageal involvement, 6 had pulmonary scleroderma, 1 had gastric scleroderma, 1 had intestinal scleroderma, and 4 had laryngeal involvement and were hoarse. Seven patients received relaxin intravenously for 3 to 7 days in increasing doses varying from 2.5 to 80 mg. in 5% dextrose and isotonic sodium chloride solution. After preliminary intravenous administration, a gel preparation was given intramuscularly in doses ranging from 30 to 50 mg. 2 to 7 times a week. Four patients subsequently received rectal suppositories containing 40 mg., taken each night. All patients were primed with diethylstilbestrol in doses of 1 mg. daily, and this was continued throughout therapy. Duration of treatment ranged from 7 to 23 months.

Relaxin helps to loosen the skin of patients with scleroderma. Sympathectomy combined with relaxin and diethylstilbestrol therapy brought greater flexibility of the skin in 8 of the 11 patients, being most effective in the face, neck, upper and lower arms, chest, abdomen, and legs. The hands showed a little improvement, such as healing of ulcers or erosions, but finger mobility was rarely improved. Relaxin seems to have a better effect in sympathectomized areas of the skin. In 2 patients who had received relaxin before sympathectomy, the skin showed no definite improvement, but in 3 patients who received relaxin immediately after sympathectomy, the skin of one was notably improved; the second patient showed improvement in the unsympathectomized facial, cervical, and arm skin but only slight improvement, as yet, in the sympathectomized area of the leg with an ulcer; the third patient died after treatment was started. Further loosening of the skin resulted in 4 of 6 patients in whom relaxin therapy was begun 4 months to 4¾ years after sympathectomy when improvement had reached a plateau.

One patient with severe pulmonary scleroderma was twice saved from acute pulmonary decompensation by vigorous therapy with relaxin given intravenously. Notable improvement of the voice occurred in 2 patients with laryngeal involvement, one of these being able to sing again. In one patient leg ulcers, which had been present for 23 years and persisted after lumbar sympathectomy, finally healed on relaxin therapy. In another patient with a leg ulcer, who had undergone only a thoracic sympathectomy, the ulcer healed in 2 months on relaxin suppositories when desultory therapy with intramuscular injections had failed. Improvement of dysphagia was notable in 4 of the 9 patients with esophageal scleroderma; 8 of the 9 patients in whom scleroderma of the esophagus had been revealed by x-ray examination still showed evidence of the disease by barium swallow. Three of the 11 patients died: one died of esophageal involvement; one with intestinal involvement died of unknown cause; and one died of an anaphylactoid reaction after intravenous administration of relaxin.

Pseudohypoparathyroidism: The Seabright Bantam Syndrome. C. W. Laymon and A. Zelickson. A. M. A. Arch. Dermat. 79:194-201 (Feb.) 1959 [Chicago].

Pseudohypoparathyroidism is a rare disease characterized by tetany and convulsions, low serum calcium level with elevation of serum phosphorus level, symmetrical obesity with round full facies, stubby fingers, acalcification of dental roots, and mental retardation in some patients. There is a failure of the appearance of phosphorus diuresis after the intravenous administration of parathyroid extract. Pseudohypoparathyroidism has the same symptomatology, chemical findings, and physical signs as hypoparathyroidism, but the cause of the disturbance is a resistance to, rather than a lack of, parathyroid hormone. It seems likely that there is an end-organ (kidney) failure to respond to parathyroid hormone, which results in the chemical aberrations in the blood of patients with pseudohypoparathyroidism.

The skin is not especially helpful in diagnosis of pseudohypoparathyroidism, since there are no constant or pathognomonic cutaneous lesions. In most cases collected from the literature, the skin was not mentioned. In some patients whose cases were reported by other workers, there was cutaneous dryness and coarseness, facial hypertrichosis, thinning of the fingernails, sparseness of hair on the scalp, face, and axillas, and scaly lesions at the angles of the mouth. Flushing of the face was mentioned in one case. The authors report on a 2½-year-old girl with pseudohypoparathyroidsim who had lichenified plaques on the face and neck simulating seborrheic dermatitis and lesions on the scalp which resembled psoriasis. The entire skin of the patient was dry and scaly, resembling ichthyosis. Microscopic examination of a dry scaly plaque on the right forearm showed moderate hyperkeratosis of the epidermis. There were scattered islands of parakeratosis and accumulations of inflammatory infiltrate in the papillary portion of the cutis. The primary disease of the patient was steatorrhea. Although the cause of pseudohypoparathyroidism is unknown, it seems to be hereditary rather than acquired. Steatorrhea may play a role in some cases.

Laboratory Studies in a Series of Biologic False-Positive Reactors. J. L. Miller, M. Brodey and J. H. Hill. A. M. A. Arch. Dermat. 79:206-212 (Feb.) 1959 [Chicago].

The authors report on 79 patients, between the ages of 23 and 82 years, most of whom were from the dermatological department of the Vanderbilt Clinic in New York but some were seen in private practice. All the patients had a biological false-positive reaction to one or more of the standard tests for syphilis and were subjected to a variety of laboratory tests, one or more of which showed abnormality in 57 of them. The 79 patients were divided into 2 groups. Sixty-seven patients (15 men and 52 women) showed no clinical evidence of disease, except for the finding of a biological false-positive reaction to the standard tests for syphilis, with a known mean duration of this reaction for 5 years; 47 of these showed abnormalities in the laboratory tests done. Twelve patients (1 man and 11 women), with a biological false-positive reaction of mean duration for 3 years, had clinical evidence of systemic disease. The diagnoses made in these 12 patients included rheumatoid arthritis, Laennec's cirrhosis, congenital hemolytic anemia, cryoglobulinemia, cerebral vascular accident, systemic lupus erythematosus, diabetes mellitus, brain tumor, migratory polyarthritis, convulsive disorder, and generalized lymphadenopathy. Ten of these 12 patients had positive results of the laboratory tests to which they were subjected. The second group of patients listed as systemic, in contrast to the first group listed as nonsystemic, thus had a higher proportion of positive results of the laboratory tests.

The laboratory tests, in the order named, were those showing the highest incidence of abnormality: serum electrophoretic pattern (showing a wide variation in the type of derangement in the serum protein level), cephalin flocculation, thymol turbidity, erythrocyte sedimentation rate, and complete blood cell count. The performance of these tests is advocated in patients with biological false-positive reactions to one or more of the standard tests for syphilis. The diagnosis of biological false-positive reaction is always of serious significance. It is commoner and of more concern especially in young women because of the higher incidence of systemic lupus erythematosus in this group. Despite the serious significance of a biological false-positive reaction, many of the patients with this finding exhibited no apparent ill-effects over many years. These variations are present in many chronic diseases. Alertness to the potentialities, careful observation, and laboratory studies are at present the best means of defense.

UROLOGY

Perirenal (Gerota's) Fascitis. J. A. Hutch, R. C. Atkinson and G. S. Loquvam. J. Urol. 81:76-95 (Jan.) 1959 [Baltimore].

Sudden complete anuria due to compression of both ureters by a dense, grayish-white mat of fibrous connective tissue, which also involves the abdominal aorta and inferior vena cava, was described by Ormond in 2 patients in 1948. Since then 19 similar cases have been described in the literature, and in this paper the authors present 2 new cases and a 5-year follow-up on one of the previously reported patients. They emphasize that this urologic entity should be distinguished from periureteritis plastica; it is an inflammatory disease confined within the perirenal (Gerota's) fascia. The first of their 2 patients died 4 days after admission to hospital. The second patient was operated on and survived. Anuria is the cardinal symptom. In 8 of the 23 patients complete anuria developed suddenly, and in 2 others oliguria developed. The remaining patients probably would have become anuric but for the surgical intervention. During the preanuric phase the urologic nature may not be recognized. Several patients were first investigated on the orthopedic, neurological, medical, or surgical services before the urologic aspects became evident. The clinical pattern is that of chronic, rather than acute, disease. A palpable mass over the sacral promontory is pathognomonic, but it was noted in only 2 of 23 cases. The authors believe, however, that, as this disease becomes better known, urologists will be able to palpate this mass more frequently. In roentgenologic visualization of the upper urinary tract, the segment of the ureter involved in the plaque lies medial to the normal position.

Previous pathological studies on small bits of plaque obtained by biopsy revealed dense, fibrous connective tissue with some fat and inflammatory cells. Autopsy studies on the fatal case presented here revealed a plaque-like mass of dense, grayish-white fibrous connective tissue that extended superiorly from a level just below the sacral promontory for 14 cm. It was 6 cm. in width at its widest point and 3 cm. in thickness at its thickest point. This plaque completely surrounded the aorta and both ureters and incompletely surrounded the inferior vena cava. The ureters seemed to be pulled medially, and their lumens were obliterated by compression. The peritoneum was densely adherent to the plaque. In addition, several loops of the small intestine adhered to the peritoneum over the plaque at the level of the sacral promontory. Multiple microscopic sections revealed that this is a benign process.

Treatment may furnish a clue to diagnosis, since in 6 of 7 patients, in whom anuria was treated by bilateral ureteral catheterization, the disease recurred when the catheters were withdrawn. The patients improved and the uremia diminished as long as the ureteral catheters were in place and draining well. Once the diagnosis has been established, the safest procedure is to institute nephrostomy drainage immediately. The surgical attack on the obstructing tissue may be handled in several ways. In some cases the transperitoneal approach is used. The second operative approach is the standard retroperitoneal incision. The problem of freeing the ureter varies, and after it has been solved, further contact between the ureter and the plaque must be prevented. The ureter has been sutured to the peritoneum or psoas muscle with an absorbable (catgut) suture. It is also possible to sew the peritoneum or the perirenal (Gerota's) fascia to the psoas in such a way that the ureter is deprived of any further contact with the scar tissue plaque. Unfortunately, even after the ureter has been freed, hard fibrotic areas still remain. The results of treatment leave much to be desired in that 4 of the 23 patients have died, and, of the remaining 19 alive when last seen, 7 had lost one kidney and several had residual damage in the remaining kidney.

Discussing the differential diagnosis between perirenal fascitis and periureteritis plastica, the authors point out that in the 4 patients with the latter condition described by Vest and Barelare Jr. the disorder was unilateral, whereas in all 23 of the cases reviewed here it was bilateral. Furthermore, in the cases of Vest and Barelare Jr. the ureters were in their normal positions, whereas in perirenal fascitis the ureters lay medial to their normal positions. In periureteritis plastica the ureter was attached to the lumbar muscles rather than being pulled medially against the vertebral bodies or vena cava or aorta. Although these 2 diseases have some features in common (compression of the ureter by periureteral inflammation and a similar histological pattern of the periureteral tissue) and may be related, the authors believe that they are separate entities.

Unilateral Multicystic Kidney: Report of 6 Cases and Discussion of the Literature. M. G. Fine and E. Burns. J. Urol. 81:42-48 (Jan.) 1959 [Baltimore].

Unilateral multicystic kidney is a congenital disorder, resulting from fetal maldevelopment, in which an irregularly lobulated mass of cysts of varying size completely replace the renal tissue. Many other terms have been applied to this disorder, but the authors are of the opinion that "unilateral multicystic kidney" describes this defect most accurately. When they encountered 2 infants with this disorder within a period of a few weeks, they reviewed the literature and searched the records of Charity Hospital of Louisiana, New Orleans, for the past 20 years for similar cases. They were able to find only 48 antomically proved cases in the literature. In addition to the 2 aforementioned infants, they found 4 others whose cases were recorded at Charity Hospital. The histories of these 6 infants are descibed. Of the 19 males and 29 females whose cases were collected from the literature, 32 were infants or children. Calcification was present in 14 patients, almost all adults, 2 of whom had osseous changes. Cartilage was found in the specimens of 3 children. In 43 cases a definite ureteral abnormality varying from complete absence to stenosis was present. In 6 cases congenital anomalies of other organs were present.

No entirely satisfactory etiological explanation for this nonhereditary congenital defect has been offered. In gross appearance the unilateral multicystic kidney has been likened to a bunch of grapes. Microscopically, the cysts are lined with a single layer of flattened or cuboidal epithelial cells, and the walls are composed of fibrous tissue sometimes with hyaline or calcific changes. These cystic kidneys may cause no symptoms. Usually a unilateral, lobulated, nontender, movable mass is palpated in the flank or abdomen of an otherwise healthy infant. Pressure on the adjacent intestines sometimes causes gastrointestinal symptoms. Pain, fever, hematuria, pyuria, and hypertension are rare. The presence of a lobulated unilateral renal mass in an infant or child with no demonstrable renal function and the absence or blind termination of the ureter on the affected side with an apparently normal functioning kidney on the opposite side should suggest the diagnosis. The prognosis following nephrectomy is good.

The Dissolution of Renal Phosphatic Calculi by Retrograde Irrigation. J. S. Elliot, J. P. Adamson and L. Lewis. J. Urol. 81:56-60 (Jan.) 1959 [Baltimore].

Elliot and associates report their experience with the dissolution of renal phosphatic calculi in 9 patients, 8 of whom were young adults severely paralyzed by poliomyelitis. They resorted to the use of citric acid solution, after they had found that Versene solution caused too much discomfort. The use of citric acid solution to dissolve phosphatic calculi was first reported by Albright, Sulkowitch, and Chute in 1939. These authors also showed that calcium oxalate calculi were insoluble in citric acid and suggested means whereby the composition of a stone might be inferred from the clinical findings and x-ray pattern. A solution less irritating than the original and containing magnesium was later described by Suby, Suby, and Albright. Since citric acid readily supports bacterial growth, the authors modified the solution described by Suby, Suby, and Albright by the addition of sodium benzoate in a concentration of 0.1%.

The irrigation is carried out with 2 polyethylene whistle-tip ureteral catheters, a size 5F and a size 7F or 8F. These are passed cystoscopically up to the involved renal pelvis. The eyes of the catheters are placed as nearly as possible in the midpoint of the renal pelvis. The smaller catheter is used for inflow, and the larger for outflow. The solution is run into the inflow catheter by continuous gravity drip at a rate of about 1 to 2 drops per second, and the outflow catheter is connected to gravity drainage by polyethylene tubing. The irrigation is continued day and night until dissolution is accomplished, or the procedure is terminated for other reasons.

In 2 patients rather large aggregates of renal calculi were completely dissolved, as were a number of recurrent calculi in a third patient. Chronic urinary infection which had been resistant to treatment responded to antimicrobials after dissolution of the calculi. In 5 other patients a marked reduction in the amount of calculous material was seen on x-ray examination. The calculi which underwent complete dissolution consisted of multiple small spherules, and all were known to have been present for less than one year. The calculi in one patient which were unaffected by the treatment were known to have been present for more than 3 years. Complete dissolution seems to be most feasible in the patient with multiple small calculi of relatively recent origin. The large staghorn calculus is less suitable for this type of treatment in view of the extended hospitalization required and the technical difficulties and complications which may be encountered. The citric acid irrigation treatment appears to be a reasonably safe procedure, provided that close nursing supervision is available. Unlike renal surgery, it may be repeated any number of times without increased technical difficulties.

The Management of Cystinuria and Cystine-Stone Disease. D. R. Smith, F. O. Kolb and H. A. Harper. J. Urol. 81:61-71 (Jan.) 1959 [Baltimore].

In contrast to the older concept that cystinuria is due to an "inborn error of metabolism," it is now generally believed that in patients with cystinuria the renal tubule is congenitally defective, insofar as the reabsorption of cystine, lysine, arginine, and ornithine is concerned. Since cystine is insoluble at the normal pH ranges of urine, formation of stones can occur, and then cystinuria becomes clinically important. Any patient who has passed renal stones in childhood, who has many recurrences, or who has a family history of renal stones should be investigated for cystinuria. All relatives of a patient with cystinuria should also be screened. The disorder is inherited as a recessive trait. One of the patients observed by the authors had 11 relatives with cystinuria. Only those with strongly positive tests, however, are likely candidates for stone formation and must be watched. The presence of typical hexagonal cystine crystals is diagnostic of cystinuria. These crystals are often difficult to find in dilute or alkaline urine. If glacial acetic acid is added and the urine is allowed to stand in a wide-bottomed flask in the icebox overnight, crystals can often be found in the centrifuged sediment. A quantitative assay of cystine excretion is likewise essential. When stones are available for examination, the diagnosis is simple. The typical yellowish, smooth, multifaceted stone permits diagnosis at a glance. The authors urge patients to bring in any stones passed previously. A roentgenogram is then taken of them on dental film in order to evaluate the density and homogeneity of the stone. Almost all ureteral stones will pass spontaneously, but a few will require cystoscopic manipulation or surgical removal. It is wise to postpone the surgical removal of asymptomatic cystine stones until an effective therapeutic regimen has been instituted, since the patient with uncontrolled cystinuria can form new stones rapidly.

Attempts were made to increase solubility of cystine by alkalinization, or to decrease its concentration by forcing of fluids, but they were not entirely satisfactory, especially in patients with severe cystinuria. The results of measures designed to decrease cystine output by chemical means, such as choline, or by low-protein diets have not been encouraging. The demonstration that methionine in dietary proteins is the principal source of exogenous cystine induced the authors to try a diet with a low-methionine content in 2 of their 4 patients with cystinuria who excreted extremely high amounts of cystine (3,000 to 3,600 mg. per 24 hours) and in whom alkalinization and forcing of fluids alone had failed to stop stone formation.

The essentials of a low-methionine (and cystine) diet are presented in an appendix to this paper. In the 2 patients receiving this diet, the authors found a notable and continuous reduction in the urinary excretion of cystine, arginine, and lysine. Moreover, there were no ill-effects (such as weight loss, asthenia, and anemia) for periods as long as 18 months. In one of the patients newly formed stones decreased in size; one stone disappeared, and the others became small enough to be removed cystoscopically. Both patients are now stone-free; their rates of cystine excretion are less than 600 mg. per 24 hours, i. e., in the range that forcing of fluids and some alkalinization can easily control.

Although the low-methionine diet may not be the final answer, at present it appears to be the most effective means of reducing cystine excretion in severe cases. The authors believe that the treatment of every patient with cystinuria must be individualized, and that the quantitative excretion of cystine is the basis for rational therapy, as well as for judging prognosis.

OPHTHALMOLOGY

Pseudotumor Cerebri or Benign Intracranial Pressure. O. Sitchevska. Am. J. Ophth. 47: 215-219 (Feb.) 1959 [Chicago].

The author presents the history of 2 girls, aged 5 and 7 years, respectively, with pseudotumor cerebri. The first patient, who had impairment of vision with marked bilateral papilledema and retinal hemorrhages, responded well to a right subtemporal decompression. However, there was pallor of the optic disks due to secondary optic atrophy, and the vision was reduced to 20/50 in the right eye and to 20/40 in the left eye. The second patient, in whom lumbar puncture revealed that the cerebrospinal fluid was under increased pressure, recovered spontaneously and had good vision and normal visual fields.

The author presents a brief review of the literature, pointing out that most reports on this condition were published in the neurological journals. Patients with failing vision or diplopia, however, may first consult ophthalmologists. The condition was first described by Nonne under the term "pseudotumor cerebri," in 1904. Other names given to the syndrome are meningoencephalitis serosa, serous meningitis, otitic hydrocephalus, or arachnoiditis, all characterized by chronic cerebral edema. A recent history of a head trauma, general infection, or otitis media is given by some patients. The true cause remains obscure. The intracranial pressure is increased, although there is no intracranial neoplasm. The onset is insidious, and the patients appear in good health. Papilledema is invariably bilateral. Headaches are frequent. Paralysis of one or both abducens nerves is common. The spinal fluid is under increased pressure, but its cell count and protein content are normal. Ventriculography reveals that the ventricles usually are small and symmetrically placed as if they were compressed by general swelling of the brain or by excessive fluid in the meninges. The visual acuity is reported to be impaired to a greater degree in pseudotumor cerebri than in elevated intracranial pressure due to a neoplasm. This syndrome usually occurs in young persons. It sometimes terminates in spontaneous recovery.

The Problem of Unilateral Amblyopia: A Preliminary Study of 10,000 National Health Patients. R. B. W. Cole. Brit. M. J. 1:202-206 (Jan. 24) 1959 [London].

Routine examination of 10,000 consecutive men, women, and children under the Supplementary Ophthalmic Service of the National Health Service disclosed that no fewer than 527 (5.27%) had unilateral amblyopia. This condition is colloquially known as "lazy eye." In 1% of all the patients examined, one eye was registrably blind, and in another 2% one eye had such poor vision as to be quite useless. In the remaining 2% of amblyopic patients the vision was so poor that binocular vision was absent. If this finding were extended to the population at large, it is apparent that, of every 100 children born, between 5 and 6 are destined to lose the use of one eye. Of the 527 amblyopic patients, 225 were male and 302 female. With an average distribution of 415 males and 585 females among 1,000 patients examined, the true sex incidence of amblyopia was 5.42% among males and 5.14% among females. There is a strong element of heredity in amblyopia, but its exact pattern is not known. Among the 527 patients with amblyopia, this condition involved the right eye in 224 (42.5%) and the left eye in 303 (57.5%). When the 527 patients were analyzed according to age groups, it appeared that in every group there was a significant number of amblyopic patients. The youngest amblyopic patient discovered was 4 years old, and the oldest was 85 years of age.

This condition of unilateral amblyopia is well known throughout the civilized world as a source of wastage of man-power in times of national emergency. Its economic and social disadvantages are equally serious, especially should anything happen to the good eye. An amblyopic patient is usually ignorant of his disability, relying unconsciously on his good eye. Unfortunately the condition develops in infancy and early childhood, and by the time the child starts school, it too often has become permanently established. Although the National Health Service offers free and comprehensive medical care of the entire population, the unexpected gap in the medical eye service, shown by the still continuing development of one useless eye in 5 out of every 100 children, is due to the fact that the first compulsory or general examination of children's eyes takes place after they have started school, when unilateral amblyopia is already well established. Early and regular ophthalmic examination of all children is indicated if this disability is to be attacked.

The Surgical Treatment of Herpetic Keratitis. M. Fine. California Med. 90:121-125 (Feb.) 1959 [San Francisco].

Corneal transplantation is at the present time the treatment of choice for controlling or terminating recurrent or chronic herpetic keratitis. Of the 48 keratoplastic operations carried out on patients with various forms of corneal herpes, 16 were performed on patients with quiescent keratitis, and 32 on patients with active keratitis. The operation brought about improvement in all but 3 patients. Recurrence of keratitis in the graft is particularly likely to occur if the visible lesion is not excised completely and if a portion of the graft border lies in contact with the diseased tissues. The reason why corneal transplantation is improving herpetic keratitis is unknown. In patients with chronic stromal herpes the removal of the necrotic corneal tissue by transplantation of cornea appeared to influence promptly and favorably the course of the disease. Even in patients in whom the transplant has not remained completely clear, the congestion of the globe was greatly relieved, often within a few days after operation, and uveitis subsided.

THERAPEUTICS

Hydrochlorothiazide in the Treatment of Congestive Heart Failure. A. N. Brest and W. Likoff. Am. J. Cardiol. 3:144-147 (Feb.) 1959 [New York].

Hydrochlorothiazide (Esidrix), a new orally administered diuretic, was given to 20 patients with congestive heart failure. In 16 of the 20 patients, the congestive failure was successfully controlled with the aid of this diuretic. Of the 16 patients, 4 had never been treated with diuretics and were given 50 mg. of hydrochlorothiazide either once or twice daily; 3 patients had been controlled only with the aid of diuretics and were given 50 mg. of hydrochlorothiazide twice daily; 9 patients had been refractory to treatment for congestive failure and were given 50 mg. of hydrochlorothiazide 3 times per day. Of the remaining 4 patients, 2 were improved, but their congestive failure was not completely controlled; 1 patient was unable to tolerate the drug because of severe nausea; and 1 patient failed to show any diuresis while receiving hydrochlorothiazide. A mild hypochloremia developed in all patients who were maintained on hydrochlorothiazide, but no significant changes in serum sodium or potassium level were observed. No deleterious hematological or renal changes occurred. The only side-effect observed was nausea, and only in one patient was this severe enough to prevent the continued administration of hydrochlorothiazide.

Evaluation of Chlorothiazide in the Diuretic Therapy of Congestive Heart Failure. L. J. Warshaw. Am. J. Cardiol. 3:167-179 (Feb.) 1959 [New York]

Chlorothiazide was administered orally to 98 adult patients with clinical evidence of fluid retention amenable to diuretic therapy; 61 of these patients had congestive heart failure, 13 had heart disease with cardiac failure precipitated by endocrine imbalance, and 24 were noncardiac patients with fluid retention secondary to endocrine imbalance. Except for 17 patients with acute decompensation, all the patients were treated on an outpatient basis. No attempt was made to standardize the dose of chlorothiazide. Most of the patients were given a single dose of 1 Gm. of the drug administered orally each morning. Many of the patients required a second dose of 1 Gm. in midafternoon. In 3 patients who seemed resistant, increased doses up to 4 Gm. daily for several days were tried, but proved to be no more effective. Chlorothiazide alone, in doses ranging from 1 to 2 Gm. daily, satisfied the diuretic requirements of 85 (87%) of the 98 patients. Patients previously maintained on mercurials administered parenterally required more frequent doses of chlorothiazide to achieve comparable results. Instances of lack of effectiveness and development of tolerance appeared to be somewhat more frequent than with parenterally administered mercurials, but much less frequent than with any other currently available, orally administered diuretic.

Chlorothiazide showed no significant local or systemic toxicity other than a few instances of gastrointestinal irritation. Low potassium levels of the blood were noted in a few patients, but none of the clinical disturbances associated with potassium depletion were seen. Chlorothiazide is a satisfactory orally administered diuretic both for the initial treatment and for the maintenance of patients with congestive heart failure. Its ease of administration does not eliminate the necessity of continued careful observation and the individualized adjustment of dosage schedules to meet each patient's changing requirements.

The Management of Congestive Heart Failure with a Free Salt Intake. I. S. Eskwith. Am. J. Cardiol. 3:184-191 (Feb.) 1959 [New York].

The author reports on 14 men and 9 women, between the ages of 26 and 83 years, with congestive heart failure who were placed on a regimen of digitalis, diuretics, and a free sodium intake. Chlorothiazide in doses of 0.5 Gm. 3 times daily for one week, and 0.5 Gm. twice daily for maintenance, was used as the mainstay of diuretic therapy, with a priming injection of a mercurial diuretic. Free salt intake was permitted. There were 2 exceptions to this general treatment scheme. A 62-year-old woman was given 2 cc. of meralluride weekly because of intolerance to chlorothiazide. A 73-year-old man had moderate intolerance to chlorothiazide and continued with only 0.25 Gm. of the drug, given twice daily. Results were excellent in 19 of the 23 patients, fair in 3, and poor in 1. Dyspnea and/or edema completely disappeared in the 19 patients who became relatively fully active. Incomplete relief of edema or dyspnea resulted in the 3 patients, or for at least 2 years they were without an attack of decompensation. Fifteen of the 23 patients had blood urea nitrogen determinations performed, which showed no evidence of renal insufficiency or progression of an existing insufficiency.

Patients appreciate the greater freedom in dietary intake they now enjoy. It is the author's feeling that restriction of sodium in the management of this syndrome is ineffective, except in the mildest cases, and that its continued use is superfluous with the diuretics now available. It is also postulated that the regimen of digitalis, chlorothiazide, mercurial injections when needed, and a free salt diet will eliminate many electrolyte disturbances now observed in patients with congestive heart failure.

Critical Considerations on Therapy with Massive Doses of Prednisolone in Patients with Malignant Hemoblastoses. J. Böhnel and A. Stacher. Klin. Med. 14:19-25 (Jan.) 1959 (In German) [Vienna].

The authors report on 9 women, between the ages of 19 and 51 years, on a 50-year-old man, and on a 7-year-old boy; 4 of these patients had acute granulocytic (myeloblastic) leukemia, 5 had Hodgkin's disease, 1 had lymphosarcoma, and 1 had carcinoma of the thymus. These patients were given an average dose of 250 mg. of prednisolone (Delta-cortril) by mouth daily for 7 to 15 days. In the patients with acute leukemia the treatment with such massive doses of prednisolone did not show any advantages as compared with that with smaller doses. The patients with Hodgkin's disease had such excellent remissions as had never been obtained with other types of therapy. This was of particular importance in patients who had become resistant to cytostatic therapy; prednisolone therapy made it possible to resume treatment with other cytostatics after intervals of weeks or even months. Temporary regression of the tumor resulted from prednisolone therapy in the patient with lymphosarcoma, and temporary subjective improvement occurred in the patient with carcinoma of the thymus. Complications of prednisolone therapy consisted of ulcer of the stomach in 1 patient and of increased hemorrhagic diathesis resulting from thrombopenia in 7 patients, 3 of whom died of cerebral hemorrhages. Physiological effects resembling those observed in patients with adrenal cortical hyperfunction (Cushing's syndrome) were observed in all the patients but were less pronounced than those occurring after prolonged cortisone therapy.

The mechanism of action of the glucocorticoids, particularly when administered in massive doses, has not been fully explained. The glucocorticoids do not exert a direct effect on the cells, but may act rather by "induced reactions and metabolites." Despite the reduced coagulation potential, thromboses may occur. Before an unequivocal explanation of the action of the glucocorticoids has been found, treatment with massive doses of prednisolone should be limited to patients with Hodgkin's disease and lymphosarcoma, who have become resistant to treatment with cytostatics and to cortisone therapy with small doses. In patients with acute leukemia the increased risk of complications outweighs by far the insignificant advantages of massive dosage.

Cycloserine and Viomycin in Combined Treatment of Pulmonary Tuberculosis: A Comparative Study. I. Ståhle. Acta tuberc. scandinav. 36:83-97 (no. 2-3) (In English) [Copenhagen].

After reviewing earlier investigations on the tuberculostatic antibiotics, cycloserine and viomycin, the author describes investigations designed to test the action of new combinations of tuberculostatics in patients with pulmonary tuberculosis. The combinations studied were cycloserine-isoniazid and cycloserine-viomycin, and the results obtained were compared with those of a third combination PAS-isoniazid. The cycloserine preparation used was cycloserine tartrate. The combination cycloserine-isoniazid was given to 28 patients, cycloserine-viomycin to 30, and PAS-isoniazid to 34.

The tuberculostatic effect, evaluated both clinically and roentgenologically, was comparable for all 3 combinations and was somewhat better for those that included cycloserine. Healing of cavities was especially good with the combination cycloserine-viomycin. The resistance of tubercle bacilli to the antibiotics could be determined only before the institution of treatment, because in all patients tubercle bacilli disappeared from the sputum quite rapidly. Initial resistance to cycloserine-isoniazid was observed in one patient who had not been treated with cycloserine previously. The tolerance for both cycloserine and viomycin was excellent, and no side-effects attributable to these antibiotics were observed. Symptoms of intolerance to PAS and isoniazid appeared in a few of the patients. The author concludes that cycloserine and viomycin are of great value in the combined treatment of patients with pulmonary tuberculosis, particularly when used together.

PATHOLOGY

Perineal Carriage of Staph. Aureus. M. Ridley. Brit. M. J. 1:270-273 (Jan. 31) 1959 [London].

Cultures were made from each nostril and 16 skin sites and press plates were taken from the front and back of the drawers of 50 medical students. By impressing an area of the inside of the drawers directly on the surface of the medium in a Petri dish with a circular wooden block, cultures were made from the perineal area. The results of this investigation showed that 26 (52%) of the students had no Staphylococcus pyogenes var. aureus in the nose or on the skin and that 13 (26%) had these organisms in the nose, generally in very large numbers, but the perineal area yielded fewer than 30 colonies from the 6 sites chosen for examination. A further 6 students (12%) had much greater degrees of contamination of the perineal area and were heavy nasal carriers as well. The remaining 5 students (10%) had an equal degree of contamination of the perineal area, but no staphylococci in the nose or only 1 or, at most, 5 colonies. Thus, sufficiently large numbers of Staph. pyogenes var. aureus were isolated from the perineal area of 22% of male adults to class them as perineal carriers.

Repeated nose and skin tests were carried out on most of the nasal and perineal carriers revealed by the initial tests. These repeated tests and additional studies showed that the carrier state may persist for months in 14% of the persons tested, that it is not due to fecal contamination alone, that the organisms are able to multiply in or on the perineal skin, that they may be of a different phage type from those found in the nose or feces, and that they may be dispersed into free air when the carrier exercises in a cubicle of plastic curtain material for 15 minutes by waving his arms about while wearing his ordinary everyday clothing.

The reported findings show that a comparatively large proportion of persons have sufficient numbers of Staph. pyogenes var. aureus on the skin of the perineum and adjacent structures to suggest that the organisms are able to colonize this area. Many of these persons have the organisms in the nose as well, while a few are primarily perineal carriers with few or none in the nose. In such persons multiplication of staphylococci on the perineum appears to be the most likely explanation for the persistence of large numbers in this site for considerable periods of time. Both the nasal vestibule and the perineal skin are areas in which large apocrine glands are found. It may, therefore, be that these glands offer a suitable environment for the survival and multiplication of Staph. pyogenes var. aureus.

Renal Papillary Necrosis: Clinical Study of 14 Patients. J. Jornod. Helvet. med. acta 25:669-693 (Dec.) 1958 (In French) [Basel, Switzerland].

Fever, prostration, nausea, and pain in the lumbar region were the most frequent, but not uniform, symptoms of renal papillary necrosis in 14 patients in whom the disease was diagnosed on autopsy. The observed biochemical changes were normochromic anemia, high white blood cell count, increased erythrocyte sedimentation rate, low serum cholesterol level, fat infiltration of the liver, elevated glycemia not necessarily related to diabetes, and symptoms of acute renal insufficiency. Frequent instances of pyuria and isosthenuria were accompanied by occasional recordings of slight albuminuria and slight hematuria. Roentgenologic findings, such as enlarged and extended calyces, hollow shadows, and contracted rings, may have suggested the presence of renal papillary necrosis, although the diagnosis must be complemented or confirmed by microscopic examination of the urine or by surgery. The histological findings disclosed necrosis of the renal papillae, being mostly a bilateral condition. This process is limited by the infiltration of leukocytes and is associated with interstitial nephritis. Its pathogenesis is attributed to hemodynamic and histochemical disorders, which are not yet understood. The disease has no sex or age group preference. A differential diagnosis of renal papillary necrosis should be made with acute pyelonephritis, acute renal insufficiency accompanied by anuria, infarction of the kidney, hematuria, thrombosis of the renal vein, renal or ureteral lithiasis, renal tumor, and tuberculosis.

Medical treatment of renal papillary necrosis is delusive. Surgical treatment (nephrectomy) is contingent on an early diagnosis of the disease, on the general state of the patient's health, and on functional integrity of the other kidney. Prophylaxis of renal papillary necrosis is based on the treatment of infections of the urinary tract and on the treatment of conditions which predispose to the development of these infections, such as malformations of the urinary tract, enlarged prostate, and the presence of diabetes mellitus.

Relation Between Systemic Histiocytic Sarcomatosis and Leukemia: Consideration of Two Instances Classified as Leukosarcomatosis. P. C. Gamalero and E. Segagni. Minerva pediat. 10:1491-1498 (Dec. 15) 1958 (In Italian) [Turin, Italy].

The authors observed in 2 boys, aged 7 and 8 years, respectively, the onset and progressive course of lymphosarcomatosis, followed by fatal lymphocytic leukemia. The mother of the younger boy had disorders of the pituitary body. This boy began to have intermittent febrile episodes a month before hospitalization. On admission, a mass, diagnosed as a lymphoma, was roentgenologically observed in the mediastinum. Histological examination of a resected enlarged right axillary lymph node revealed the presence of lymphosarcomatosis. Examination of the peripheral blood and the sternal puncture showed no pathological change. The older boy had had a suppurative inguinal lymphadenitis on the right 2 years before admission. In addition to pallor, he developed cough, intermittent fever, and enlarged cervical, axillary, and inguinal lymph nodes a month before admission. Examination at the time of admission revealed enlarged spleen (on inspection) and enlarged lymph nodes in the mediastinum (on roentgenologic observation). Histological examination of a peripheral lymph node suggested the diagnosis of lymphoreticulosarcoma. Morphologic examination of the peripheral blood revealed the presence of lymphocytosis. Sternal puncture disclosed the existence of reticular lymphoid cells.

A combination of drug therapy (corticotropin), blood transfusion, and antihemorrhagic treatment, followed by a course of roentgenologic therapy, brought temporary relief to the 2 patients. But a fatal clinical picture of acute lymphoid leukemia of short duration appeared in both boys shortly after completion of the x-ray therapy. This clinical picture (known as leukosarcomatosis) is a contribution to the theory that postulates a pathological nexus between the appearance of sarcomatous neoplasm of the lymph nodes and the subsequent development of acute leukemia.

Staphylococcal Septicaemia. J. E. Hassall and P. M. Rountree. Lancet 1:213-217 (Jan. 31) 1959 [London].

This report is based on 86 cases of generalized staphylococcic disease that occurred during the 8 years from 1950 to the end of 1957 at the Royal Prince Alfred Hospital in Sydney, Australia. In this large hospital, generalized staphylococcic infection occurring in patients after admission with other illnesses was not a problem before 1952. Since then numerous cases have occurred. The number of patients admitted with staphylococcic septicemia has also increased sharply since 1954. Study of the histories of the patients, and sometimes of the phage type of Staphylococcus organisms isolated, placed the patients in either the group infected outside the hospital (46) or the group who acquired their infection in the hospital (40). The criteria for diagnosis of generalized infection with coagulase-positive staphylococci included one or more of the following: (1) clinical evidence of generalized infection, together with culture of the organisms from one or more sites; (2) growth of organisms from blood culture; and (3) pyogenic lesions of the internal organs found at autopsy, together with culture of the organisms from these lesions or from the blood.

Of the 40 patients who were infected in the hospital, 31 died. The infecting staphylococci belonged to only a few phage types. These infections started in 1952, and all followed surgery, intravenous therapy, or the exhibition of cortisone. Of the 46 patients who acquired their infections outside the hospital, 19 died. Up to 1954 there was an average of 2 such cases each year, but the incidence rose notably in the 3 following years. This increased incidence was due almost entirely to infections with strains of phage type 80/81. In 1957 the mortality rate in both categories of patients fell. This decline coincided with keener awareness of the problem of staphylococcic cross infection, earlier diagnosis of septicemia, and intensive treatment with effective antibiotic combinations.

PUBLIC HEALTH

Cancer and Bronchitis Mortality in Relation to Atmospheric Deposit and Smoke. P. Stocks. Brit. M. J. 1:74-79 (Jan. 10) 1959 [London].

Residents in large towns of England and Wales have always been subject to higher death rates than country dwellers. Two diseases for which the urban excess is pronounced are bronchitis and lung cancer, and this is so in some regions for gastric cancer, whereas cancers of the intestine and breast show little relation to urbanization. Atmospheric pollution of the kind found in British towns has been under suspicion as a causative agent both for bronchitis and for lung cancer, and the author suggests that pollution of food by exposure to dirty air might be a cause of the higher incidence of gastric cancer in towns. He describes an attempt to obtain more conclusive evidence on these points by relating standardized mortality from bronchitis and cancers of 4 sites, with measurements of atmospheric deposit and suspended matter (smoke), in the county boroughs of England and Wales and in the administrative areas of Lancashire and the West Riding of Yorkshire, where such measurements have been made.

Throughout his report the author refers to the standardized mortality ratio (S. M. R.), which means 100 times the actual deaths of residents in an area divided by the number which would have occurred if the death rates at each age had been the same as the rates for England and Wales as a whole. He found that, when the S. M. R.'s for bronchitis and cancers in the county boroughs of England and Wales are related to the average amounts of undissolved deposited matter and smoke from the air in towns, highly significant statistical correlations are found for bronchitis and lung cancer with both types of pollution after eliminating the effects of population density on the correlations. In all administrative areas in Lancashire and the West Riding of Yorkshire having the necessary pollution data, bronchitis is significantly correlated with deposit but not with smoke, while for lung cancer the reverse is the case. In Lancashire areas lung cancer is strongly correlated with population density in adjacent districts even when that of the area itself is held constant, and this appears to confirm the effect of wind-borne smoke on the incidence of the disease.

Stomach cancer mortality is related significantly with both undissolved deposit and smoke in the county boroughs, and among women in the Lancashire and Yorkshire districts also, whereas breast cancer shows negative correlations in the county boroughs and no relation with air pollution in the counties. The most likely explanation of this is the exposure of food to dirty air, and this hypothesis is supported by the fact that in the United States, where wrapping of food was the rule long before it began to be practiced in Britain, death rates from stomach cancer have fallen steadily in contrast to their lack of improvement in Britain. Intestinal cancer also shows small correlations with deposit and smoke in the county boroughs, but these correlations are below the conventional level of significance.

Admission of Patients with Alcoholism to General Hospitals in New York State. I. J. Brightman, C. M. Royle, B. Ferber and others. New York J. Med. 59:237-247 (Jan. 15) 1959 [New York].

The authors made a survey in New York State of general hospital policies in regard to admission of patients with a primary diagnosis of alcoholism. Of 356 general hospitals to which a questionnaire was mailed, 315 returned the appropriate forms answering the questions. About 20% of voluntary general hospitals and 35% of public general hospitals indicated that their policies provided for the admission of alcoholic patients. Only 9% of proprietary general hospitals admitted such patients. Only 50% of the nonadmitting hospitals stated that their regulations precluded their accepting alcoholic patients. About 40% of the admitting hospitals found the patients to be not too troublesome, and almost all found that tranquilizing drugs were particularly helpful. A surprisingly large proportion of alcoholic patients paid for part or all of their care or had such payments made in their behalf. The figures present a state-wide picture only, and it may be expected that there will be much variation when the situations are studied on a community base. It is hoped that the communities will study their local problems and attempt to encourage the admission of alcoholic patients to general hospitals, if this policy has been deficient in the past. A comparable study of proprietary hospitals for nervous and mental diseases indicated that 15 out of 16 admitted alcoholic patients.

Five Years' Experience with Fluoridation in Norway, Maine. A. H. Garcelon. New England J. Med. 260:127-129 (Jan. 15) 1959 [Boston].

The town of Norway, Maine, began fluoridating its water supply on Oct. 17, 1952. An earlier report presented evidence that beneficial effects began to become apparent in children, 6 to 9 years old, within 30 months after fluoridation was started. The present study was designed to determine what effects fluoridation had on the permanent teeth of children, 6 to 14 years old, who used the fluoridated water supply continuously for the first 5 years after fluoridation was started. Between 1952 and 1957, the average numbers of decayed, missing, and filled permanent teeth were reduced by more than half among the children, 6 to 9 years of age, by more than a quarter among the children, 10 to 12 years of age, and by about a tenth among those, 13 and 14 years old. During the same interval, the percentage of children, 6 to 9 years old, who were entirely free of dental decay in permanent teeth more than doubled.

Except for one group, which was too small, the differences in rates are all statistically significant. Hence, children, 6 to 14 years old, who used the fluoridated water supply continuously after fluoridation was started received significant benefits from the first 5 years' fluoridation, even though in some of them many of their permanent teeth had erupted before fluoridation began. Since the maximum benefits of fluoridation occur when the fluoride is incorporated in the tooth enamel while it is being formed, the younger children, who had more of their teeth formed under fluoridation, received greater benefit than the older children. Since the beneficial effects continue undiminished throughout life once the decay-inhibiting effect is established, as succeeding generations are brought up on the fluoridated water supply, an increasing proportion of the population of Norway, Maine, will benefit from fluoridation.

BOOK REVIEWS

Cardiac Arrest and Resuscitation. By Hugh E. Stephenson Jr., M.D., Professor and Chairman, Department of Surgery, University of Missouri School of Medicine, Columbia. Cloth. $12. Pp. 378, with 31 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1958.

Considering the importance of the subject of cardiac arrest and resuscitation it is surprising that this is the first comprehensive monograph to be written about it. It is not surprising that its editor should be Dr. Stephenson, since no one man has shown a more intense interest in the subject. He has been helped in this effort by several authoritative contributors. The book is all-inclusive, with chapters on history, incidence, etiology, diagnosis, management, prevention, complications, and prognosis. The author is to be commended for including a chapter on the care of the patient in the postresuscitative period, as this phase of the subject has been neglected. He has not, however, given hypothermia the emphasis it deserves as a means of preventing permanent neurological defects. Of added interest also are the chapters on the medicolegal aspects of cardiac resuscitation and elective cardiac arrest in open-heart operations. This book should be a welcome addition to the library of any surgeon. The chapter on the prevention of cardiac arrest is especially worthwhile.

The English Health Service: Its Origins, Structure, and Achievements. By Harry Eckstein. Foreword by James Howard Means, M.D. Harvard political studies published under direction of Department of Government in Harvard University. Cloth. $5.50. Pp. 289. Harvard University Press, Cambridge 38, Mass.; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, England, 1958.

This volume describes and evaluates the origins and 10 years' performance of England's National Health Service (NHS). The unplanned growth of medical care is traced from the poor laws of the 1830's through the compulsory health insurance of 1912 to the present arrangement. The conditions existing prior to enactment of the National Health Service and allegedly necessitating its introduction are characterized as "deplorable" on the testimony of the Collings Report. The proclaimed objectives of the NHS were to increase the supply of medical services and to rationalize the system. As achievements of the NHS the author cites geographical redistribution of physicians and, to a lesser extent, hospital facilities; an increase in the number of physicians and apparent improvement in their financial security; and at least no deterioration in doctor-patient relationships.

The author condones the shortcomings of the NHS in part because of the shortage of all kinds of resources to meet Britain's postwar needs. The shortcomings include negligible expansion of hospital facilities—"only 3,000 beds represent an absolute increase in capacity" by 1955 and "capital expenditures on hospitals in 1952-53 were only 32 per cent of those in 1938-39 [in real values]"; aggravation of this condition by abuses of the NHS; and lack of coordination and cooperation between isolated regional hospital boards and particularly between many local authorities, hospitals, and general practitioners. The author doubts that the well-known defects of multilevel bureaucracy under one powerful minister have modified the practice of medicine, although he admits, for example, that the method adopted to classify procedures has resulted in paying surgeons more for an easy operation than for a difficult one.

Physicians' dissatisfaction with the remuneration under the NHS is well known. The author seems too disposed to attribute shortcomings of the NHS to the "deplorable" preexisting conditions. He does not adequately define his tests and criteria of evaluation. Data are not plentiful, and he does not seem to have considered any other alternatives to either the preceding or the present system. We admit that socialization appears to be an irreversible process, but some modifications would seem to be conceivable. His discourse on planning (in the epilogue) is inappropriate, revealing shortcomings in his understanding of a market economy as well as a decided preference for planning. Although he found rational action lacking under a "rational system," using the NHS as a test, he still urges planning of an imperfect variety. His additional recommendation that the Minister of Health "go on a spending spree" reveals another bias.

One of the most profound issues, "whether there can be any price system at all (in the classical sense) in such areas as medicine," is relegated to a footnote. The author apparently does not know of "opportunity cost," yet it is well known that when the price of one item of consumption is reduced to zero, overconsumption inevitably results. To the extent that satisfaction of additional (free) health wants is less valuable to the British citizenry than that of the nonhealth wants consequently foregone, the NHS is costly indeed. Moreover, when varied wants are equalized through zero price, the less valuable may be satisfied (through spectacles and dentures) prior to the more valuable (through new health centers). For these reasons the author's efforts to demonstrate that the system is not costly

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

are superfluous and unconvincing. The definitive study of England's National Health Service is yet to be written.

Comprehensive Medical Services Under Voluntary Health Insurance: A Study of Windsor Medical Services. By Benjamin J. Darsky, M.A., Nathan Sinai, Dr.P.H., and Solomon J. Axelrod, M.D., M.P.H. Bureau of Public Health Economics, School of Public Health, University of Michigan, Ann Arbor. Cloth. $7.50. Pp. 392, with illustrations. Harvard University Press, Cambridge 38, Mass.; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, England, 1958.

Comprehensive physicians' services can be provided under voluntary health insurance sponsored by a local medical society on a fee-for-service basis. This conclusion is based on the study of Windsor (Ontario) Medical Services (WMS), Inc., made in 1954 under a grant from the Health Insurance Foundation by the Bureau of Public Health Economics of the University of Michigan. The recent growth of a series of experiments providing for the payment of physicians' services outside the hospital under different Blue Shield and other voluntary health insurance plans makes this first large-scale study of the operation of a similar plan of great interest. The report provides detailed information on the background and organization of the WMS; the use of physicians' home and office services, and services for hospitalized illnesses; the attitude of the public and the local medical profession toward the plan; the physician-patient relationship under the WMS; claim administration; and the effects of the plan on medical practice in Windsor.

On the basis of a survey of the Windsor population and physicians, and a survey of records, it was concluded that the medical profession and the subscribers support and approve WMS; WMS is financially stable and administratively sound; both the physician and the patient are satisfied with the method of control; and medical care is "adequate and sound," with the subscribers to WMS initiating care more frequently than other people in the community. The value of this pioneer effort in research is hampered by the limitation of the study to the techniques of the social scientists. Judgments on medical care were made on the basis of replies to questionnaires by both patients and physicians, and not on the basis of the medical management of cases. As a basis for comparison with future studies, the bench marks used (services provided by physicians) may be of limited applicability. The nature of medical care is constantly improving. Services that had meaning at one time may not be of such great value a decade later. What comparisons can future physicians make with these service bench marks?

Although the WMS does not include payment for direct hospital charges, the authors found the use of the hospitals was slightly greater than for non-WMS members. Similar differences were found in studies of the Saskatchewan Health Services Plan, but studies in New York City by the Health Insurance Plan showed that hospital use was less under their plan than under a plan providing Blue Shield coverage. What caused these differences between the United States and Canada? Was it chance, or something inherent in the practice of medicine in certain areas of Canada? The present study, unfortunately, does not provide analysis of the critical points of variations and differences that evolved in the Windsor area. A great deal of comparison is made between the persons with WMS and those covered by other plans. One area of interest would have been an analysis of the premiums paid by those enrolled in other plans. The reader does not learn whether the scope of services provided under the WMS was a reflection of higher premiums paid by subscribers or due to the inherent nature of the operations of WMS. As with every research study, some flaws may be found, but the book provides a clear and reasonably complete exposition of the history and administration of a voluntary health insurance plan providing comprehensive physicians' services.

Progress in Medical Virology. Volume I. Edited by E. Berger and J. L. Melnick. Cloth. $11.50. Pp. 304, with 44 illustrations. Hafner Publishing Company, 31 E. 10th St., New York 3; S. Karger AG., Arnold Böcklinstrasse 25, Basel, Switzerland, 1958.

Despite the recent proliferation of various biological publications there is ample justification for a review series on the medical aspects of virology. Such a publication should keep clinicians and clinical investigators informed of advances in fundamental virology and should summarize and correlate the literature of viral disease. The editors seem to have had these objectives clearly in mind when planning this first volume in a projected series. On the fundamental level there are articles dealing with the structural and functional aspects of virus particles and the significance of persistent virus infections in tissue culture. Of more direct interest to the clinician are the reports on the 1957 pandemic of influenza and the critical review of the techniques used in preparing and evaluating poliomyelitis vaccine.

The editors have gone out of their way to obtain a truly international representation. There are articles from South Africa, the U.S.S.R., India, England, and the United States. With the wealth of material available in modern virological studies, and the ever-growing variety of virus diseases, it is difficult to understand the inclusion of articles which are redundant to the extent that several are concerned with similar diseases. Thus there are two articles dealing with diseases caused by the Russian spring-summer complex of viruses. There is also one article on the enteroviruses, including considerations of the clinical features of Coxsackie virus infection and another on neonatal myocarditis caused by the same virus. The redundancy is largely at the level of the subject material and not the content. A single efficient review article might have permitted the inclusion of a greater variety of topics.

The quality of the articles is uneven. Colter's review of nucleic acids and viral infectivity performs a useful service in collating pertinent information from animal, plant, and bacterial viruses. He enlivens his article with a critical consideration of some of the controversial topics in this snowballing field. Another rapidly growing field, that of persisting virus infection in tissue culture, is reviewed by Ginsberg. The potential importance of these investigations as a model for understanding the role of "latent" virus infections in man needs little emphasis. It was disappointing, however, to find no reference to the careful work of Vogt and Dulbecco, which perhaps contributed more than any other study to our understanding, at a cellular level, of the mechanism by which a virus persists in at least one of the carrier culture systems. It is perhaps even more difficult to understand the omission of any reference to the venerable but growing literature on the continuous production of tumor viruses by infected cells in vitro.

Melnick provides a thorough picture of the enteroviruses, including their fundamental physical and biological characterization as well as their clinical and epidemiologic significance. This article might serve as a prototype for future articles in the series, although few are as qualified as the author to present such a multifaceted picture. McClean and Taylor's article on poliomyelitis vaccine is an instructive analysis of the various steps involved in its manufacture from growth of the virus through inactivation and safety and potency testing. They make a convincing case for the technique of combined ultraviolet light and formalin inactivation of poliovirus. Their method for improving the safety test by simply increasing the volume of fluid tested per tissue-culture bottle is unconvincing in the absence of some supporting data. For instance, we know that if the volume of inoculum on a monolayer is increased beyond a certain point, the virus is not efficiently adsorbed.

It is difficult to understand the inclusion of Smith's article on virus flocculation reactions. The likelihood that these will replace the standard diagnostic tests now in use appears miniscule despite Smith's arguments to the contrary. The space might better have been used for a review of the practicable techniques available today. This criticism is not meant in any way to detract from the potential usefulness of the flocculation techniques in fundamental investigations of the nature of viruses. The paper on the Asian influenza epidemic is a welcome and highly competent review of a subject of great importance. The rest of the articles are best characterized as competent. The books suffers seriously from the absence of an index. A detailed table of contents preceding each article would also be useful. There is a disconcerting number of typographical errors in the text, and the quality of the binding, considering the price, is not impressive. Nevertheless, the series promises to fill an important need, and the succeeding issues are anticipated with the hope that criticisms will be taken kindly and to heart.

Poisoning by Drugs and Chemicals: An Index of Toxic Effects and Their Treatment. By Peter Cooper, F.P.S. Cloth. 25 *shillings*. Pp. 209. *Alchemist Publications*, *Thomas Waide* & Sons, Ltd., 25 Oxford St., London, W. 1, England, 1958.

This handbook is a compilation of 350 monographs on potentially toxic drugs and chemicals. The monographs were developed from an extensive collection of case reports of accidental poisoning and information from standard reference books on pharmacology and clinical and industrial toxicology. Each monograph includes a list of synonyms; concise notes on dosage, pharmacological action, toxic effects, and possible effects of massive overdose; suggestions for treatment; and simple aids for identification of the toxic substance. Occasionally abstracts of published cases are included. An appendix provides first-aid measures for the emergency management of poisoning, and a comprehensive index lists generic, proprietary, chemical, and common names. One of the particular merits of a book of this type is its brevity and clarity. By summarizing pertinent facts, it provides the concise and precise information required in poisoning emergencies.

Obstetric and Gynecologic Milestones: Essays in Eponymy. By Harold Speert, M.D., Assistant Professor of Clinical Obstetrics and Gynecology, Columbia University College of Physicians and Surgeons, New York. Cloth. $15. Pp. 700, with illustrations. The Macmillan Company, 60 Fifth Ave., New York 11; Brett-Macmillan, Ltd., 132 Water St., S., Galt, Ontario, Canada, 1958.

Most of the chapters in this delightful book are devoted to one historic person. The sections deal with anatomic parts and landmarks; measurements; clinical signs, tests, and rules; phenomena of pregnancy and labor; bacteria; ovarian tumors; syndromes; positions, instruments, and operations; and therapeutic procedures. It is well indexed. Every obstetrician and gynecologist should be delighted by the book, both for its historic value and as a reference work. There are many original illustrations and portraits. From the beginning of history men's names have become part of our language, often to the point where they are spelled with small letters. Every science and art contains these eponyms, which are a tribute to the men involved. The author states that the use of proper names in anatomy has long been disputed, and in 1855 a commission could not agree and compromised by allowing their retention in brackets after the objective Latin names. Their fate was to be decided by time and general usage. Such terms as eustachian tube, Glisson's capsule, and circle of Willis are too deeply entrenched to be uprooted.

The book is a compilation of essays, about half of which have been previously published in journals, so it is more or less a chronological record of the development of obstetrics and gynecology. Each chapter gives some history and background concerning the subject under discussion. Many of the feuds and conflicts concerning contemporary names with original prints, excerpts, and translations of original texts are shown. The intentness, precision, and thoroughness that some of the early men of medicine demonstrated is discussed. The accuracy of the material is praiseworthy, and the controversies seem to be presented in an unbiased fashion. In general these men were broadly educated and were often heads of such departments as physics or chemistry before assuming the chair of medicine. Many were young when they received the Doctorate of Medicine. Whether the use of eponyms in medicine is good or bad is debatable, but unless a man's name is attached to an instrument, disease, or anatomic part he is soon forgotten. Famous men, dead less than five years, are unknown to today's young physicians. This excellent book promises many years of rewarding reading.

Surface and Radiological Anatomy for Students and General Practitioners. By A. B. Appleton, W. J. Hamilton, and Ivan C. C. Tchaperoff. Fourth edition by W. J. Hamilton, M.D., D.Sc., F.R.S.E., Professor of Anatomy in University of London at Charing Cross Hospital Medical College, London, and G. Simon, M.D., B.Ch., D.M.R.E., Demonstrator of Radiological Anatomy in Medical College of St. Bartholomew's Hospital, London. Cloth. $9.50. Pp. 355, with 416 illustrations. Williams & Wilkins Company, 428 E. Preston St., Baltimore 2, 1958.

The new edition of this well-established textbook by an anatomist and a radiologist emphasizes the dynamic and functional aspects of topographic and radiologic anatomy. By the use of radiology the reader is given a clear picture of body structure as it appears in the living subject. The value of radiology in the teaching of gross anatomy is generally accepted in medical schools. This book should be useful to the student of anatomy, as it correlates topographic and radiologic anatomy by parallel illustrations of surface contours and reproductions of radiographs of the underlying structures. This edition has been extensively rewritten, revised, and rearranged. The subject matter is organized on a regional basis with separate chapters devoted to general anatomy and methods, upper limbs, chest and back, head and neck, vertebral column, and lower limbs. The text is liberally illustrated with excellent radiographic reproductions, photographs, line drawings, and diagrams. By extensive use of illustrations the authors provide a means of coordinating radiologic anatomy with surface landmarks determined by external examination and those details which can be determined only by dissection. This excellent, well-illustrated textbook is strongly recommended to undergraduate and postgraduate medical students and to students in such fields as x-ray technology, physical therapy, and physical education.

Emergency War Surgery: U. S. Armed Forces Issue of NATO Handbook Prepared for Use by the Medical Services of NATO Nations. United States Department of Defense. Cloth. $2.25. Pp. 411, with 18 illustrations. Superintendent of Documents, Government Printing Office, Washington 25, D. C., 1958.

As stated in the first chapter the purpose of this pocket-sized manual is to present "the principles and techniques of emergency care of casualties through the first three echelons; that is, the battalion aid station, the clearing station, and the field or evacuation hospital." The problems of definitive care of injured patients are excluded. The handbook is written in a clear, concise, and comprehensive manner which should enable it to fulfill its purpose in a most satisfactory manner. In addition, with a few modifications, this handbook should be useful to the civilian surgeon faced with the problem of caring for civilian injuries.

The contents are divided into four parts: The first deals with types of wounds and injuries, the second with response of the body to wounding, the third with general considerations of wound management, and the fourth with regional wounds and injuries. In addition, a glossary of drugs with national nomenclatures and several useful tables are included in the appendixes. There are excellent chapters on missile wounds, burns, cold injuries, crush injuries, blast injuries, chemical injuries, and radiation injuries. The management of patients with the various conditions considered is sound, and a section at the end of each chapter is devoted to the management of mass casualties. Problems of sorting patients with single and multiple injuries are well presented. The section dealing with regional wounds and injuries is particularly well done.

In some areas the civilian surgeon must greatly modify his approach to the injured patient from that presented in the NATO handbook. For example, he should be mindful of the fact that civilian missile injuries are generally of a much lower velocity than those of battle wounds; consequently, débridement of missile tracts must be more conservative. Similarly, in dealing with intestinal injuries, the civilian surgeon is permitted to take a more conservative approach. As a means of acquainting the newly commissioned military surgeon with the management and methods of evacuation of casualties, this volume should find a field of great usefulness, and, considering its size, the extent of detail is remarkable.

QUESTIONS AND ANSWERS

LEUKEMIA AFTER IRRADIATION

To the Editor:—*A 37-year-old man with rheumatoid spondylitis was treated with deep x-ray therapy. In 1946 he had a total of 1,600 r to both sacroiliac joints over a period of four weeks. In 1947 he had a total of 1,200 r divided equally over the cervical, thoracic, and lumbar portions of the spine. Is the development of leukemia in this man a foregone conclusion? If not, what are his chances of developing leukemia?*

Edward J. Novak, M.D., Tuckerman, Ark.

Answer.—In some patients leukemia does occur after exposure to ionizing irradiation, but, as Warren (*J. Mt. Sinai Hosp. New York* 24:1331, 1957) said, "Radiation is not the sole factor in production of the disease." The fear of leukemia developing after irradiation of the spine is founded mainly on the report of Court-Brown and Doll (Leukaemia and Aplastic Anaemia in Patients Irradiated for Ankylosing Spondylitis, Medical Research Council, Special Report Series, no. 295, London, Her Majesty's Stationery Office, 1956), who noted that there was an appreciable incidence of leukemia in veterans treated by x-ray over a prolonged period for ankylosing spondylitis. These findings, however, have not been observed by others using similar methods of therapy. In those patients in whom leukemia was noted, it followed long periods of exposure, often repeated, to x-ray. In the past 35 years, this consultant has treated with x-rays many patients who had arthritis, and leukemia subsequent to this treatment has not been observed. In the patient under discussion, the dose of x-ray given was not excessive or beyond usual therapeutic limits. Treatment was not persistent, and there was an appropriate interval between treatments. It is, therefore, not a foregone conclusion that this man will develop leukemia, nor is the chance of his developing this disease very likely.

AMEBIC GRANULOMA

To the Editor:—*How should amebic granuloma of the cecum be treated?* *M.D., Texas.*

Answer.—No information is given in the question regarding age, sex, signs, and symptoms referable to a particular patient. It is, therefore, assumed that information of a general nature is being sought. Amebic granuloma (ameboma) is a rare complication of intestinal amebiasis. It is usually single and consists of a firm, nodular mass with a fibrous outer wall. It may be well localized, involving a small area of the colon, or it may occupy an extensive segment of the large intestine and contiguous tissues. The intestinal wall may be greatly thickened. The mass consists usually of an inner zone made up of necrotic tissue containing red and white blood cells, fibrin, and amebas and associated with varying degrees of sloughing; a middle zone formed principally of granulation tissue with profuse chronic inflammatory elements and superficial or deep abscesses containing few or many amebas; and a completely fibrotic outer zone. Amebomas occur most commonly in the cecum and rectum. Spicknall and Peirce (*New England J. Med.* 250:1055, 1954) gave the location of 230 amebomas in 197 cases as follows: cecum, 40.9%; ascending colon, 3.1%; hepatic flexure, 2.2%; transverse colon, 9.5%; splenic flexure, 2.2%; descending colon, 1.7%; sigmoid, 5.2%; rectum and anal canal, 26.5%; and no location given, 7.4%. Carcinoma of the colon is the most important lesion to be distinguished from ameboma. The two may coexist. Appendiceal abscess, diverticulitis, actinomycosis, benign tumor, tuberculous enteritis, regional enteritis, and other conditions in which a mass may be associated with diarrhea should be considered in the differential diagnosis.

No single drug should be used in the treatment of ameboma. The following combination of antiamebic and antibacterial drugs is likely to give the best results: emetine hydrochloride, 0.06 Gm. intramuscularly, given once daily for not more than five days, together with chloroquine phosphate, one 0.25-Gm. tablet, given four times daily on the first day and thereafter twice daily for a total of 21 days. In patients in whom a differential diagnosis between ameboma and another inflammatory lesion cannot be made conclusively or in whom ameboma is associated with bacterial infection, emetine treatment should be followed by therapy with chlortetracycline or oxytetracycline, 0.25 Gm., given four times daily for 10 days simultaneously with chloroquine. The chloroquine therapy may be followed by a course of glycobiarsol therapy, 0.5 Gm., given three times daily for 10 days, or with diidohydroxyquinoline, 0.5 Gm., given four times daily for 20 days, to eradicate the associated intestinal infection. In most patients the

Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

above regimen will cause the disappearance of the lesion within a month of the beginning of treatment.

USE OF GLUCOCORTICOIDS

To the Editor:—*This dispensary treats a number of patients with allergic rhinitis and bronchitis, chronic disabling conditions for which treatments are generally unsatisfactory. In some patients the results are poor, there are unpleasant and even dangerous side-reactions, or high probabilities exist that long-continued treatment will produce an unfavorable patient-treatment relationship through the appearance of refractoriness or sensitization. The glucocorticoids have offered some hope of solving this problem, for they are extremely potent and can in some cases be used locally, thus avoiding some of the side-reactions. They are appearing in such bewildering variety, however, that it is hard to keep up with them. With each new product the general practitioner wants to know not only its side-reactions but also its proclivity for changing the patient, or the disease, into a less manageable state with this or related drugs and, particularly, how such side-reactions or proclivity are affected by use of the agent locally, such as in nose-drops or inhalation spray. One reason this is hard to decide is that the manufacturers seem to devote little attention to such items. Since this area is somewhat isolated and large medical libraries are not readily accessible, please recommend a recent, general evaluation of the glucocorticoid drugs with regard to the long-term management of allergic conditions, insofar as these can be distinguished from rheumatic conditions.* *M.D., California.*

Answer.—The glucocorticoids are generally considered to be of unequivocal value in affording symptomatic relief in patients with allergic diseases of the nasal or bronchial mucosa that are resistant to the usual forms of treatment. Their widespread use is limited, however, by the fact that they merely control the symptoms without attacking the underlying cause and by the high incidence of undesirable side-effects that they elicit. Attempts have been directed toward preparing new compounds with powerful anti-inflammatory properties and free from deleterious actions, but so far these have met with limited success. Prednisone and prednisolone are more potent on a weight of drug basis than cortisone and hydrocortisone and cause less sodium retention and potassium depletion, advantages in the treatment of patients with hypertension or heart disease. The incidence of other side-effects, however, is not appreciably reduced. Methylprednisolone, triamcinolone, and dexamethasone are even more powerful than prednisolone and prednisone, but they have not been used long enough to establish whether they offer a more favorable therapeutic ratio. Preliminary reports indicate, for example, that triamcinolone may give rise to weight loss, profound muscular weakness, and cutaneous erythema, effects that have not been observed with the other steroids. Fludrocortisone has about 25 times the anti-inflammatory action of cortisone but is such a potent sodium-retainer that it can only be used topically for the management of allergic conditions; even then, sufficient absorption may occur to produce sodium retention and edema. Local use of steroids, by inhalation or instillation, has been shown to be effective in the treatment of such conditions as bronchial asthma and allergic rhinitis. Prednisone and prednisolone, being water soluble, permit nebulization. Hydrocortisone and cortisone must be administered as a powder or in the form of a suspension. The advantage of this route is that much smaller amounts of the drugs are required. Systemic absorption is, therefore, limited in degree, and the cost of the drugs is reduced. Few long-term studies have been reported.

There is little information concerning the development of refractoriness to steroids in the treatment of such conditions as asthma and allergic rhinitis. Some investigators have reported lessened effectiveness in the relief of hay fever in subsequent seasons, but this is not a uniform finding. Others report a definite loss of activity with continuous use of steroids in asthma, but again there appears to be wide individual variation in this respect. Patients may become habituated to steroids after prolonged use, so that withdrawal becomes a problem even if the patient is seemingly deriving no benefit from the drug. There is no evidence that the steroids render other types of therapy any less effective. In fact, patients who have failed to respond to such preparations as epinephrine or aminophylline prior to steroid therapy may respond to these drugs after alleviation of their symptoms with steroids.

EXCHANGE TRANSFUSIONS

To the Editor:—*How are donors chosen for exchange transfusions? The serum of the donor chosen for the first transfusion of a group O, Rh-positive baby with a group O, Rh-negative mother was crossmatched with the mother's serum. The second pint of blood, used from another donor and crossmatched with the mother's serum, was found incompatible in minor crossmatch—the donor's blood was not crossmatched with the baby's blood. If more than one pint is used, should the donor's blood be crossmatched with both mother's and baby's blood? If the blood is found incompatible in any phase, should that donor be rejected?*

William E. Arbuckle, M.D., Indianapolis.

Answer.—In general, newborn babies are incapable of forming antibodies, and any antibodies present in their serum represent maternal antibodies passively acquired by placental transfer. This permits a wide latitude in the method of selecting donors for treating erythroblastotic babies by exchange transfusion. In the typical case of erythroblastosis fetalis, where the mother is Rh-negative and the baby Rh-positive, Rh-negative donors must be used for the exchange transfusion, because Rh-positive blood can react with the maternal Rh antibodies present in the baby's blood. Wiener and Wexler prefer to use Rh-negative donors of the mother's A-B-O group. The advantage of this is that the donors can be selected before the baby is born and the mother's serum can be thoroughly checked during the antenatal period for its content of abnormal isoantibodies. If the mother's serum contains no abnormal isoantibodies other than anti-Rh_0, there is no valid reason why Rh-negative donors of the mother's A-B-O-group cannot be used even without crossmatching. There need be no hesitancy giving group A blood to a group O baby when the mother belongs to group A, because the baby's serum will have no alpha antibodies and such blood will survive in the baby's circulation as long as group O blood.

If crossmatching tests are done, only the major match is essential, because the baby's red blood cells are going to be removed by the exchange transfusion in any event. Since any antibodies the baby may have are derived from the mother, the mother's serum should be used for the matching test if this is done, and this has the additional advantage that the mother's serum is easier to obtain than the baby's. It is not clear why a minor crossmatching test was made in the case described or why any incompatibility should have been detected in the minor crossmatch, since the donor and mother were both group O and Rh-negative. Most likely the reaction obtained was an artifact such as is not common in these tests, though the possibility that the donor's serum contained an irregular isoagglutinin, such as anti-P, cannot be excluded. In any event, the reaction in the minor crossmatch should not necessarily disqualify the donor.

Most workers prefer to use donors of the baby's A-B-O group rather than of the mother's. Still others routinely use group O, Rh-negative donors for all cases, with or without crossmatching. If group O donors are used routinely, the blood should be titered in order to eliminate those with high titers ("dangerous universal" donors), who theoretically might be undesirable for babies not belonging to group O. The routine use of group O, Rh-negative donors, while convenient, has the disadvantage that it is apt to deplete the supply of group O, Rh-negative blood.

STERILIZATION OF CATHETERS

To the Editor:—*About 10% of the patients treated here are given intubation either by the oral or by the naso-oral (endotracheal blind intubation) approach. In sterilization of endotracheal catheters, the following technique has been used for many years and there seems to be no reason for changing this procedure: The catheters that are inserted through the nose are washed with soap and water or hexachlorophene, and then they are kept submerged in mercuric cyanide (1:3,000 solution). When they are used, they are rinsed off with ether and lubricated with a lubricating jelly. The trachea is aspirated through a small catheter which has been sterilized by the same solution. The endotracheal catheters with a built-in cuff are sterilized by the same method. They are removed from the mercuric cyanide solution, washed off or dried with ether, dusted with sterile glove powder, and kept wrapped in a sterile towel until use. At that time, the powder is washed off with ether and the balloon part of the catheter is lubricated with lubricating jelly before being inserted into the trachea. A serious vocal cord injury has not occurred. Postoperative hoarseness is rarely noted, and the incidence of postoperative lung complications has been low while this technique has been used. Is there any reason to switch to one of the newer agents?*

Eldon B. Tucker, M.D., Morgantown, W. Va.

Answer.—One hesitates to recommend changes in procedures when an inquirer states so emphatically that he has experienced no difficulty with "tried and true" methods. Most authorities in the field of antiseptics and disinfectants believe that the commonly used mercurials are poor germicides and, unless used carefully, have no place in modern disinfection. All are extremely slow to kill vegetative bacteria. No reference to the tuberculocidal or viricidal activity of mercuric cyanide has been found, although there is evidence that bichloride of mercury, a more toxic compound, in a concentration of 1:1,000 rapidly inactivates influenza and vaccinia viruses. For the destruction of vegetative bacteria, tubercle bacilli, and influenza and enteroviruses, one authority recommends flushing of rubber tubing, "shellack," and "web" catheters by syringing with Wescodyne (450 ppm available iodine), a 2% solution of Amphyl, or a 2.5% solution of Staphene, followed by immersion in the same solution for 10 minutes and rinsing and flushing thoroughly with sterile water. Other modern proprietary and nonproprietary solutions may also be effective. Thorough mechanical cleansing of the instrument should precede the above treatment. It is a moot question as to whether the excess handling required for powdering with a starch preparation (talc should not be used) and rinsing with ether is necessary with the types of catheters available today. There are a number of proprietary and nonproprietary solutions which serve satisfactorily for sterile storage of sterilized catheters.

ACTION OF TESTOSTERONE

To the Editor:—*In view of the recent development of many variations of testosterone and the conflicting claims of some of the pharmaceutical companies regarding their products, please give information on which of these are considered to be most anabolic and least androgenic when given clinical trials in human beings. Also, what attempts, if any, have been made to inhibit the antianabolic effects of corticosteroids by the use of these androgens? If such can be done, do the corticosteroids still possess anti-inflammatory activity when their antianabolic effects have been suppressed? Which of the anabolic steroids is considered the agent of choice in suppressing corticosteroid antianabolic effects? What are the relative proportions of corticosteroids to androgens which are necessary for such activity? In the presence of corticosteroids and androgens, is there any inhibition of the antiallergic effects of corticosteroids (assuming that antiallergic effects and anti-inflammatory effects are not the same)? The same question may be posed in regard to inhibition of antibody reactions, again assuming that these are not necessarily related to antiallergic and anti-inflammatory effects.*

M.D., Washington.

Answer.—Generally speaking, the greater the anabolic effects of a derivative of testosterone, the greater are its androgenic effects. Most derivatives or variants of testosterone are compared clinically to the propionic acid ester of testosterone. Testosterone propionate, when given parenterally, has greater potency and more sustained action than the naturally occurring endogenous testosterone and about four times the potency of free testosterone in oil when injected. In the average woman, monthly amounts of 300 mg. of testosterone propionate may be given without interfering with normal menses and without masculinizing effects. The dark-complexioned and brunet woman is more likely to experience these latter effects in somewhat lower dosages, due to larger amounts of endogenous androgens. The dosage of any testosterone preparation has to be individualized in each patient, depending on age, sex, state of nutrition, dietary intake, and presence or absence of disease. The antianabolic effects of the corticosteroids in normal or moderate dosages can be prevented by adequate dietary intake. When large doses are used, the antianabolic effects can be prevented by giving 25 to 50 mg. of testosterone propionate intramuscularly daily and, occasionally, at intervals of two to three times weekly. Androgen therapy does not affect the antiallergic, anti-inflammatory, and/or antibody reactions of the corticosteroids.

VITAMIN B_{12} REQUIREMENT IN ANEMIA

To the Editor:—*Does a patient with pernicious anemia, who is being well maintained on the standard dose of vitamin B_{12} given hypodermically, require more vitamin B_{12} if an infectious disease develops? If so, does the severity of the infection determine the amount of increase required? Have tests been made on such patients who have contracted infectious diseases to see whether they undergo certain blood depletions that would call for more vitamin B_{12}?*

H. Ward Randolph, M.D., Richmond, Va.

Answer.—Although it is usually stated that patients with pernicious anemia should receive an increased amount of vitamin B_{12} when a complicating infection develops, this recommendation is based largely on theoretical considerations. Fortuitous observations have occasionally shown that, when an acute infection develops in a patient with pernicious anemia during the initial reticulocyte response to vitamin B_{12}, the erythropoietic progress may be temporarily halted. In monkeys maintained on diets containing barely adequate amounts of folic acid, the creation of turpentine abscesses resulted in a megaloblastic type of bone marrow. This could be prevented by the administration of folic acid but not vitamin B_{12}. However, other than in serum hepatitis, which presumably seriously compromises the storage function of the liver for vitamin B_{12}, it has not been shown that the serum level of vitamin B_{12} is significantly reduced or urinary excretion increased by infections.

Even in normal subjects, and more obviously in patients with hemolytic anemias with no detectable evidence of vitamin B_{12} deficiency, certain types of nonbacterial upper respiratory infection may cause a temporary complete cessation of erythropoiesis with cellular hypoplasia of the bone marrow. Chronic infections are commonly associated with moderate anemia due to erythropoietic hypofunction. Characteristic is a fall of the serum iron level and of the level of iron-binding protein of the plasma. Indeed, the deleterious effects of infection on diverse biochemical functions are well known. Some, such as the increased insulin requirement in diabetes mellitus, are reversible. Thus, in theory and by analogy, it is possible that infection may create a need for more of the precursors of biochemical processes concerned with erythropoiesis, perhaps including a need for more vitamin B_{12} in pernicious anemia. Consequently, despite the lack of direct clinical evidence that more vitamin B_{12} will promote erythropoiesis in pernicious anemia during infections, the prudent physician will be well advised to at least double the maintenance dosage of vitamin B_{12} at no great inconvenience or expense to his patient.

STAPHYLOCOCCUS CARRIERS

To the Editor:—*The chairman of the infection committee in a hospital has been concerned as to what to do with the nasal carriers of coagulase-positive strains of Staphylococcus pyogenes var. aureus among key personnel of the obstetrics and surgical services. Specific antibiotic therapy based on sensitivity studies of the organism involved has been recommended. Bacteriophage typing has not been done, as facilities for this service will only accept material from patients with active cases. Some of the personnel rebel at having to take antibiotics when they feel well. Others cooperate with therapy but never succeed in showing negative results on nasal culture after supposedly adequate courses. Others have a temporary loss of nasal staphylococci but have a relapse after several months. In a small community where paramedical personnel of all types are at a premium, such persons as delivery room supervisors or surgical scrub nurses, who cannot be replaced, should not be removed from duty. How important is the role of the nasal carrier? Please give recommendations as to management of nasal carriers in such a situation.*

Helen A. Horn, M.D., High Point, N. C.

Answer.—The treatment of key personnel who have congulase-positive staphylococci in the nose and throat does not consist of giving antibiotics. In the event such organisms are there after acute infections, it is logical, either with the properly chosen sulfonamide drugs or with antibiotics, to clear up the residual infection, but in chronic carriers the usual experience is that these organisms disappear while the subject is under therapy only to reappear within a relatively short time after treatment has been discontinued. The answer to this problem consists of a return to strict medical aseptic techniques. It is largely due to the loss of this factor that hospitals now face the Staphylococcus problem. The reliance has been on anti-infective drugs rather than on properly applied aseptic techniques. Such key personnel may continue to be employed as long as they are taught the tenets of medical asepsis, washing their hands thoroughly after blowing their nose, touching their face, or going to the toilet, as well as thorough washing and rinsing at least three times before proceeding from one patient to another. Type-specific bacteriophage has been used, both as a nasal spray and by intramuscular injection, to clear up the carrier state, and good results have been reported.

PREOPERATIVE TUBERCULOSIS THERAPY

To the Editor:—*A 41-year-old Negress is scheduled to have a hysterectomy for uterine leiomyoma. She was first given the diagnosis of tuberculosis in 1949. When hospitalized she had fever, positive sputum culture, positive tuberculin skin test, massive pleural effusion, and a small, soft infiltrate in the upper lobe of her left lung. The clinical impression was miliary tuberculosis. This was never established, and she was discharged after six months' therapy with streptomycin as having minimal, inactive tuberculosis. Since that time she has had regular chest x-ray and sputum examinations. The soft infiltrate healed without residuals, and findings on x-rays of the chest were essentially negative. Sputum specimens have been negative. Her diagnosis at present is pulmonary tuberculosis, minimal and inactive (nine years), with exercise status 4. It has been suggested that she be given isoniazid for five days preoperatively to prevent relapse of her tuberculosis. If treatment is indicated, what would be a satisfactory regimen?*

M.D., Georgia.

Answer.—Negro patients with pulmonary tuberculosis are more prone to have exudative types of the disease, especially the caseous pneumonic form. This is associated with a high degree of sensitization from a diet high in carbohydrates and congestion in housing allowing for intimacy and a massive dose infection with tubercle bacilli. Negroes have thus had a tuberculosis mortality of about six times that of the white population. They also have had an average sickness interval before death of about one year, compared to three years for white patients. With the marked decline of tuberculosis mortality across the United States to about 7 per 100,000, the racial decreases in proportion to the population have been about the same. This is most likely associated with the sharp decrease in milk-borne infection and the improved economic status with resultant improvement in housing. This patient should be given isoniazid for about two weeks before and several weeks after operation. The diet should be high in protein and fat, with only the natural carbohydrates in the vegetables. The anesthesia might best be spinal, and if the red blood cell count is low or depleted during operation it should be built up by transfusion.

ORAL TREATMENT OF DIABETES

To the Editor:—*In view of the fact that treatment in the young diabetic is seldom successful with tolbutamide, please give information on what, if any, influence on the unborn child treatment of a 31-year-old primigravida with this drug would have. The patient was recently found to have a low-grade diabetes.* *M.D., Virginia.*

Answer.—Experience with tolbutamide in the management of diabetes complicating pregnancy is limited, primarily because most such patients are of an age group which characteristically exhibits a labile or "juvenile" type of diabetes. In such patients tolbutamide therapy is generally contraindicated. Probably not more than 15% of pregnant patients with overt diabetes exhibit the disease in sufficiently mild and stable form to warrant a careful trial of sulfonylurea therapy. Among those cases of diabetes complicatng pregnancy which have been reported to this consultant in the past three years, all patients were carefully selected for tolbutamide therapy because of the mild and stable character of their diabetes and several pregnancies were carried to a successful termination with delivery of healthy babies. No evidence of untoward effect of tolbutamide therapy on mother or fetus was found. It must be emphasized, however, that the pregnant diabetic is especially prone to the sudden appearance of ketoacidosis in the latter weeks of pregnancy. This complication is a major cause of fetal death. Thus, even the pregnant patient with mild diabetes, if placed on sulfonylurea therapy, must be observed with vigilance in anticipation of the possible development of acidosis and need for pharmacological doses of insulin.

Answer.—Even at the age of 31, a person with diabetes in an early stage may respond well to tolbutamide. Visceral toxic effects are seldom seen, so a favorable opinion would seem to be indicated. This consultant is unaware of any definitive evidence on this point, however, and must therefore advise the use of insulin and/or diet during the pregnancy. All investigators have been faced with the same risks in human subjects. They have been reluctant to make (or at least to report) trials, and no animal experiments have been recorded.

DUTIES OF OPERATING ROOM NURSE

To the Editor:—*An anesthesiologist who recently began private practice in a small city had, all through his training, taken the duties of the circulating nurse in the operating room pretty much for granted, especially in regard to the anesthesiologist. This was challenged recently by the operating room supervisor, and the chief of surgery and the anesthesiologist are now interested in having some references that may have been proposed in the past in answer to the question, "What are the duties of a circulating nurse in an operating room?" For example, during induction, it has always seemed a wise policy to have either the surgeon or his assistant in the room, with the circulating nurse right by the side of the patient, preferably on the side with the intravenous apparatus. The supervisor states that the circulating nurse should have no part in this role. Surely this attitude cannot be in the best interest of the patient. Please give an opinion for presentation at the next surgical staff conference.*

Harold F. Dallas, M.D., Poughkeepsie, N.Y.

Answer.—In a well-known general hospital, the duties of the circulating nurse are not described in a manner limiting her only to the duties associated with the operation. She is available to help the anesthesiologist if he needs her help, but too frequently she is expected to do many of the routine things that the anesthesiologist should do for himself, such as having syringes, ampuls of various medicaments, intratracheal tubes, and laryngoscopes immediately available and his gas machine opened up for use. The circulating nurse should not be expected to do many of these routine things, but she might be expected to lend a hand to the anesthesiologist if it would be of some assistance to him.

WATKINS' TRANSPOSITION OPERATION

To the Editor:—*Until about 1953, a surgeon who had trained in Vienna and Switzerland performed many Watkins' transposition operations in this hospital for the most severe cystoceles. This operation brings the corpus of the uterus down in front of the prolapsing bladder. This surgeon has now retired, and some of the other members of the staff will probably have to perform hysterectomies on some of these women with malignancies. Even those surgeons who have board certification have never seen the technique for hysterectomy under such conditions. Please give information on this complicated hysterectomy.*

Michael E. Connelly, M.D., Sharon, Pa.

Answer.—Uterine malignancy after the Watkins' transposition operation indeed poses a serious problem. Inasmuch as the cervix is usually amputated in this procedure, the probability is that one would be dealing with a carcinoma of the corpus. After the transposition technique has been performed, the uterus is fixed in the anterior vaginal wall in an inverted position and access to the uterine cavity for diagnostic curettage or radium insertion is difficult, if not impossible. Thus, material for microscopic examination would be difficult to obtain. Technically, vaginal hysterectomy after Watkins' operation poses no particular problems except that the operator must bear in mind the postfundal attachment of the bladder. It is not difficult to separate the anterior wall of the vagina from its attachment to the uterus. The anterior dissection usually begins at the fundal portion, and the operator works upward into the vagina. However, this is not the operation of choice for uterine malignancy. When a definite diagnosis of malignancy has been made, the following plan should be used: (1) external radiation to the pelvis; (2) a wait of six or eight weeks; (3) dissection of the anterior vaginal wall from the uterus by the vaginal route; (4) closure of the vaginal incision and continuation by laparotomy; (5) a total hysterectomy and bilateral salpingo-oophorectomy (even though the uterine tubes were detached previously), with the postfundal attachment of the bladder borne in mind; and (6) pelvic adenectomy. This plan would offer the best chance for survival.

MUSTY ODOR OF CLOTHING

To the Editor:—*The family of a 45-year-old man complains that his clothes develop a strong, musty odor, which becomes worse after he has removed the clothes and they have been sitting in a laundry basket. Physical examination of the patient gives normal findings. There are no noticeable skin lesions or body odors. Examination with a Wood's light is also negative. The patient has tried soaps containing hexachlorophene, but these have not made any difference in the odor of his clothing. Please give suggestions on study and treatment of this case.*

James F. Hohl, M.D., Ada, Okla.

Answer.—The question of body odors is an age-old problem and one on which the cosmetic industry has built a highly remunerative sales appeal. To properly answer this question it would be necessary to know (1) how long this has been occurring, (2) what kind of work the patient does and with what materials he comes in contact, (3) what his eating habits are, and (4) whether he has a special fondness for certain types of foods. Odors associated with the human body usually come from fats and may be due to faulty catabolism, that is, from changes in the sebum and apocrine gland excretions. Certain apocrine glands have a specific odor which is characteristic for the particular person and cannot be changed. The exocrine glands secrete such substances as indoles and skatoles from the intestinal tract. These odors would be largely influenced by diet. In some persons butyric acid production is high, resulting in strong odors. Since this odor develops in the laundry basket, one must consider bacterial decomposition due to presence of Clostridium bifermentans or Cl. sporogenes. Treatment is sometimes unsatisfactory if due to an inherited tendency. Otherwise, change of diet, elimination of the aromatic substances, use of such digestants as pepsin, a diastase, dilute hydrochloric acid, papain, and bile salts may be tried. The clothing may be soaked in weak potassium permanganate solution immediately on removal. The intestinal flora may be changed by the use of acidophilic preparations.

RESIDUAL FACIAL PARALYSIS

To the Editor:—*What is the value of physical therapy for a residual facial paralysis of 24 months' duration secondary to neuropathy of the facial nerve?*

Bernard Levine, M.D., Oak Park, Mich.

Answer.—Physical therapy for this condition does not usually result in any clinical improvement. Massage and other passive exercises may be of value in the correction of facial disfigurement in this stage, but this has no influence on the rate of return of motor control. Similarly, the use of electric stimulating currents at this time would have no significant therapeutic effect. It does not influence the rate of nerve regeneration in any way. In the early stages, it is useful in retarding the degree of muscle atrophy but will not prevent it completely, and after two years without return of function atrophy has usually occurred to such an extent that stimulation is without effect.

CONTACT DERMATITIS

To the Editor:—*Certain occupations, such as dentistry, dishwashing, bartending, and poultry plucking, require that people who perform them have their hands in water much of the time. Is there any chemical solution which can be used on the hands to prevent fungus growth or other skin diseases?*

T. R. Pratt, M.D., Pismo Beach, Calif.

Answer.—It is well known that occupations in which the hands are moist or wet repeatedly or for prolonged periods favor the development of dermatitis and, occasionally, also of fungus and bacterial infections. The best way to prevent such secondary complications is to minimize wetting and subsequent excessive dryness of the skin by frequently washing and drying the hands thoroughly and then applying an emollient cream. For that purpose a cold cream of good quality is usually satisfactory. Some state laws require bartenders to use a chemical agent which in itself is a deterrent to infection but which occasionally produces dermatitis. That is the handicap associated with the use of fungicides, bactericides, and the like; therefore, it is best not to recommend them for routine use. A fungus or bacterial infection, when it does develop, is usually more promptly responsive to therapy than a chemical dermatitis from use of protective antifungal or antibacterial agents. An intact normal skin is the best protection against such infection. Minor skin injuries should receive prompt and proper attention, and persons who have dermal abnormalities, such as excessive dryness occasioned by congenital ichthyosis, are more likely to develop dermatitis in such occupations and therefore should be particularly cautious in their activities.

POSTURAL VARIATIONS IN PULSE AND BLOOD PRESSURE

To the Editor:—*In insurance examinations the physician is often asked to determine the pulse and blood pressure with the applicant reclining, sitting, standing, and after three minutes of exercise. What variation should be expected in the normal person? When patients bend far backward or lean far forward for two or three minutes, some have no appreciable change in heart rate while others show a wide variation; this is a constant finding in the same person on repeated examinations on one visit and on subsequent visits. Bending backward in patients with cardiorenal disease or preeclampsia and, to a lesser extent, in those with moderate coronary sclerosis slows the heart. Bending forward gives similar results, but to a lesser degree. Why does bending forward or backward slow the pulse?*

Lloyd H. Murdock, M.D., Zwolle, La.

Answer.—The systolic blood pressure usually falls when a person rises from the reclining position. The change may amount to 10 or 20 mm. Hg in hypertensive persons. The diastolic pressure, on the other hand, is variable and may either rise or fall. The change is usually not great. The result is a drop in the pulse pressure on standing. Exercise usually raises the systolic pressure and may increase or decrease the diastolic pressure, but there is almost always a resulting increase in the pulse pressure. A slowing of the pulse rate associated with bending backward may be due to stretching and consequent stimulation of the carotid sinuses in the neck. This reflex increase in vagal tone is particularly marked in patients with coronary sclerosis. This phenomenon has not been noted consistently on patients leaning forward.

POSTOPERATIVE GENITOURINARY BLEEDING

To the Editor:—*At this hospital a high incidence of postoperative bleeding from the genitourinary tract has occurred recently. The anesthetic used, the patient's position, or the site of operation do not seem to be factors. The condition lasts for only 24 hours, but two cases of renal shutdown have occurred and both were fatal. The urine has been completely bloody, sometimes with and sometimes without cells. Transfusions do not always precede the hemorrhage. The postoperative course varies. Some patients go into shock and others have a normal postoperative course except for the hematuria. Some have indwelling catheters, and others do not. The picture is so varied that it is hard to know where to lay the blame and whether there are several factors at work. Little has been written about this, and any information would be appreciated.*

John J. Rooney, M.D., Nyack, N. Y.

Answer.—On the information given, it is presumed that imperfections in surgical technique have been ruled out. The next procedure is to have the blood being used for transfusion checked and cross-checked for correct typing. If such blood is perfectly compatible, the staff, having found a new and local syndrome, should make a detailed study of it. Such simple things as platelet count, prothrombin time, and presence or absence of serum fibrinolysins should be investigated. If staff members were greatly interested, they could carry out more elaborate studies on coagulation, though use of the three tests mentioned would probably point the way to further studies.

POSTOPERATIVE CEREBROVASCULAR COMPLICATIONS

To the Editor:—*What cerebrovascular complications are likely to occur after mastoid operations? Would carotid artery thrombosis follow such an operation? What complications might result from packing of the jugular bulb?*

M.D., Louisiana.

Answer.—The common cerebrovascular lesions associated with mastoid disease are thrombophlebitis of the sigmoid sinus, the petrosal sinuses, the jugular bulb, and, occasionally, the cavernous sinus. Thrombophlebitis of these sinuses is not as a rule a complication of mastoid operation but is the result of the disease in the middle ear, mastoid, and/or petrous pyramid for which the operation was performed. There is ample evidence that when these complications have progressed or have become evident only after operation it has been because the operation was not adequate to deal with the lesion present. Such lesions have usually been either an already existing but undetected thrombophlebitis or an undrained focus of suppuration in the temporal bone which later involved a venous sinus. Discussions of this question are found in any standard textbook, such as "Otolaryngology" (edited by G. M. Coates and others, Hagerstown, Md., W. F. Prior Company, Inc., vol. 2, chap. 15).

Carotid artery thrombosis in the neck is being increasingly recognized as the underlying mechanism in some cerebrovascular accidents. Most of these cases are spontaneous and are associated with arteriosclerosis, but the condition has been reported after nonpenetrating injuries to the neck. The article by Murphey and Miller (*J. Neurosurg.* 16:1, 1959) may be helpful.

CATARACTS

To the Editor:—*It has been thought that many more young people now than formerly are developing cataracts. If so, is there any etiological explanation for it?*

W. O. Bailey, M.D., Washington, D. C.

Answer.—There are no statistics which indicate that senile cataracts are occurring at a younger age. The cause of cataracts is unknown. There is an impression among many physicians that cataracts are developing at an earlier age. With the development of the intracapsular operation, undoubtedly immature cataracts are being operated on at much earlier stages than heretofore. This is probably the genesis of this impression.

CONGENITAL ANOMALIES

To the Editor:—*A patient belongs to blood group B and her husband to group O; both are Rh positive. She has never had any transfusions. Her first child died a few seconds after birth and had hydrops fetalis, club foot, and other anomalies. In the last month of pregnancy the patient suffered from hydramnios. Is it advisable for her to become pregnant again? What are the chances that she will have a normal child?*

M.D., New York.

Answer.—The results of the blood grouping tests in this case rule out any major blood group incompatibility, so that isoimmunization of pregnancy can probably be excluded as having any bearing on this couple's problem. It is not possible to ascertain the cause of the hydrops fetalis responsible for the baby's death; therefore, no definite statement regarding the probable outcome of future pregnancies can be made. It has been reported that fetuses with certain congenital anomalies may develop hydrops in utero, and this in turn may be complicated by the development of polyhydramnios. The cause of congenital malformations is not known, though there is evidence that hereditary factors play a role, as well as such other factors as nutrition of the expectant mother and the mother's age. Among 500 mothers who gave birth to a malformed child, Murphy found that 275 (55%) experienced subsequent conceptions and that 25 had one and 9 had two additional malformed children (Congenital Malformations, ed. 2, Philadelphia, J. B. Lippincott Company, 1947). These facts should be presented to the couple, and the ultimate decision of whether to undertake additional pregnancies must then rest with them.

INTRAOCULAR PRESSURE AND HYDRATION

To the Editor:—*What is the relationship between intraocular pressure and the underhydration or overhydration of patients? Numerous observers have observed soft eyeballs in diabetic coma and other states of dehydration, but, in states of overhydration, has an increased intraocular pressure been conclusively proved?*

M.D., Washington.

Answer.—A number of stimuli may cause transient changes in the intraocular pressure, and included in these factors is the osmotic pressure of the blood. The normal eye, however, is characterized by homeostatic mechanisms that quickly adjust the intraocular pressure to normal. The administration of a large volume of hypotonic fluid decreases the osmotic pressure of the blood plasma. Presumably the osmotic pressure of the aqueous humor is increased relatively, and dilution of the aqueous humor to the corresponding osmotic pressure results in an increased aqueous volume and an increased intraocular pressure. In the normal eye this increase seldom exceeds 5 mm. Hg within an hour of ingesting 1 liter of water. In a glaucomatous eye the pressure may increase more than 10 mm. Hg. Similarly, substances which increase the osmotic pressure of the blood, such as hypertonic glucose solution, a 5% solution of urea, sorbitol solutions, and the like, tend to decrease the intraocular pressure. There is an extremely large amount of literature on this topic. Much of it is surveyed in the review of glaucoma which appears each year in the December issue of the *A. M. A. Archives of Ophthalmology.*

HAIR LENGTH AND BALDNESS

To the Editor:—*Please give advice as to short hair versus long hair for men. Does the length of the hair have any relation to loss of hair?*

Jerome Kogan, M.D., Stamford, N. Y.

Answer.—Short hair or the cutting of hair has no relationship to receding hair or the prevention of hair loss. This fact has been verified by many separate investigations on numerous occasions.

CONTACT LENSES

To the Editor:—*What is the best type of contact lens? Is a lens with radial grooves around the outer edge advantageous in allowing free circulation of lacrimal fluid beneath the lens?*

P. M. Stoddard, M.D., Fairmont, W. Va.

Answer.—Contact lenses may be worn to improve appearance, as a substitute for spectacles where spectacles are not feasible (as in sports and certain occupations), and to obtain visual improvement not possible with spectacles (as in keratoconus or corneal scarring). There are two general types of contact lenses, each having advantages and disadvantages. Corneal contact lenses are cosmetically the most acceptable and are most easily tolerated, but they are not very satisfactory in contact sports (boxing and wrestling) and hazardous occupations. Scleral contact lenses are less satisfactory cosmetically and not tolerated as well, but they can be worn for any type of use. In most communities, the proper fitting of contact lenses requires the combined skills of the ophthalmologist and a technician trained in this work. The section of ophthalmology of the local medical society can make available the names of such persons. Contact lenses with radial grooves have the advantage of allowing the normal tears to serve as a fluid under the lens and are thought by some to be superior to those not having such grooves.

DERMATITIS AFTER EXPOSURE TO SPUN GLASS

To the Editor:—*A 52-year-old woman used spun glass to decorate a Christmas tree two years ago. She touched her forehead with it and has had an irritation of the forehead ever since. Every two to four weeks she has an eruption on her face. Burning and itching will disappear after a short time and then return. Please suggest treatment.*

E. T. Sager, M.D., Marion, Ohio.

Answer.—Spun glass is a pruritogenic substance capable of causing a dermatitis, but an eruption due to this agent would not recur every two to four weeks without further exposure. Herpes simplex or a dermatitis medicamentosa would be more apt to recur in this way. Therefore, the first step would be to make a morphologic diagnosis. There are no agents that uniformally prevent recurrence of herpes simplex. Smallpox vaccinations (one every two weeks for at least three treatments) will interrupt some cases. A careful history should be taken, and if any drugs, including self-administered analgesics, laxatives, or sedatives, capable of causing a dermatitis have been used at intervals, they should be eliminated. The possibility of a recurrent contact dermatitis should be considered also. Elimination of suspicious contactants from the patient's environment would be recommended. Patch testing may be necessary.

CARCINOMA AND THROMBOPHLEBITIS

To the Editor:—*An article stating that some types of carcinoma give rise to thrombophlebitic phenomena prompted this question: Does endometrial carcinoma give rise to such signs? A 63-year-old woman has had vaginal bleeding associated with carcinoma, but she has also had two or three such episodes in the past that led to the diagnosis of phlebitis of the lesser saphenous vein of the right leg.*

John K. Griffith, M.D., Valley Falls, Kan.

Answer.—Some types of carcinoma, particularly those of the pancreas and occasionally of the lung, give rise to idiopathic recurrent thrombophlebitic phenomena. Malignancies in the female pelvis or tumors compressing the great vein may produce stasis and cause thromboses in a pelvic vein. The fact that the patient had involvement of the same vein, the right lesser saphenous, would suggest a local process rather than a humeral mechanism, which usually produces a migratory phlebitis. A physiologist, an expert on coagulation, stated that endometrial carcinoma could theoretically increase the tendency to intravital clotting, but none of the consulted gynecologists, obstetricians, or internists have seen a patient with migratory thrombophlebitis associated with endometrial carcinoma.

SHORTENED FEMUR

To the Editor:—*During a routine examination, a 32-year-old woman said that she had had a fractured femur in 1948, with shortening of the involved limb by 1 in. She has no complaints referable to her back, but physical examination showed the expected pelvic tilt. She does not wear corrective shoes. In the course of her life is she likely to develop any disability from a pelvic tilt? Is it necessary to compensate for the limb shortening with an elevated shoe, and, if so, what would be the minimal lift required?*

J. E. Rockwell Jr., M.D., Grangeville, Idaho.

Answer.—Some heel raise would be advisable to prevent backache in the future. It is frequently not necessary to make up the entire difference, but in this case an increase of three-quarters of an inch should be provided, since a patient can compensate very well for one-quarter of an inch. This heel raise is best accomplished in stages. The heel of the short leg should be raised one-fourth of an inch and that of the higher lowered one-fourth of an inch. After about three months the heel of the short leg should be raised another quarter of an inch. This method usually is better than taking all of the correction on the affected heel.

U. S. PHYSICIANS REPORT ON RUSSIAN MEDICAL PROGRAM

A team of American doctors who toured the Soviet Union found that the Russian government has deliberately focused on quantity of medical personnel and widespread coverage of services, at the expense of quality.

According to the five U. S. physicians who visited Russia in 1957 under an exchange program the quality of service in the U. S. S. R. falls far short of that in the United States. However, the physicians reported an "almost explosive extension" of disease prevention and medical care programs in the U. S. S. R. They noted that there is a high ratio of physicians to population and that many hospitals have been built to serve rural as well as urban areas.

Not only were the Russian physicians not as well trained as their U. S. counterparts but the medical facilities and equipment were "antiquated or jerry-built" in comparison to those in the U. S., the report said.

The report, published by the U. S. Public Health Service, said that pestilential diseases and the diseases of filth have been brought under control throughout the Soviet Union, that malaria is almost eradicated and venereal disease controlled, but that tuberculosis remains a major health problem.

The mission was composed of Dr. Thomas Parran, former U. S. surgeon general and now President of the Avalon Foundation; Dr. Otis L. Anderson, assistant U. S. surgeon general; Dr. Henry van Zile Hyde, assistant to the surgeon general for public health; Dr. Malcolm Merrill, California state director of public health; and Dr. Leonid S. Snegireff, associate professor of cancer control, Harvard School of Public Health.

One of the most interesting findings of the group was that three-fourths of Russian physicians are women. The total number of Russian doctors in 1957 was 325,000, compared to about 225,000 in the U. S.

Russian medical students receive only six years of training, in contrast to the nine years in this country, and the medical schools are overcrowded, the report said. As an example, the Americans noted that only six dissecting tables were available at one school for a class of 400 students.

Medical care is free to everyone in Russia, but "there is essentially no freedom of choice of physicians by patient," and the physicians have little or no say about where they practice, the report asserted.

Russia claims 10 or 11 hospital beds per 1,000 population, the U. S. physicians said, while the ratio in the United States is 9.2 beds. However, the report cautioned that the Russian statistics lack confirmation.

Other findings of the group:

Physicians in the U. S. S. R. have less status than engineers.

Clerical help and office equipment of the type found in this country are regarded as "unheard-of luxuries" in Russia.

Political philosophy and political economy are required courses throughout the six-year medical school training.

The range of drugs used in medical practice in Russia "is much more limited in quantity and quality. . . ."

"The health program of the Soviet Union is, like all programs, subject to the needs of the state, and is therefore circumscribed by a series of allocations and goals."

RADIATION HEARINGS END ON OPTIMISTIC NOTE

A House-Senate subcommittee on atomic energy wound up an extensive investigation of radioactive fall-out dangers, and subcommittee chairman Holifield (D., Calif.) concluded that the danger "is not serious."

He made the statement after hearing scores of expert witnesses present their views on whether nuclear tests are depositing harmful amounts of radioactive matter into the atmosphere.

"It is clear now that the possible hazard is very small in comparison to the needs of our defense," said the lawmaker, who in the past has criticized the Atomic Energy Commission for allegedly withholding fall-out information from the public. "I believe testing could be resumed, if necessary, at a limited rate," he said.

The general advisory committee of the AEC told the subcommittee that the average world-wide radiation resulting from all nuclear bomb tests so far is less than 5% of the normal radiation in the air.

The advisory group, composed of nine civilian scientists and engineers, also declared that the radiation from tests was "less than 5% of the estimated average radiation exposure of the American public to x-rays for medical purposes."

Speaking of the internal effects of radioactive strontium (Sr^{90}), the group stated that the amount which has been found in food and water "is less of a hazard than the amount of radium normally present in the public drinking water supply in certain places in the United States, and in public use for many decades."

Warren C. Johnson, vice-president of the University of Chicago, is chairman of the advisory committee.

Representative Holifield said after the hearings ended that radiation from fall-out amounts to some 10% of the natural background radiation and that he believes the task of separating the effect of the 10% from the 100% is too difficult a problem ever to be solved.

Meanwhile another congressional committee took up the subject. A Senate labor and public welfare subcommittee headed by Sen. Lister Hill (D., Ala.) is considering a measure introduced by Mr. Hill that would transfer prime responsibility for radiation safety work from the AEC to the Public Health Service. The administration had no immediate stand on the issue. Arthur S. Flemming, secretary of Health, Education, and Welfare, noted that his agency, the AEC, and the Budget Bureau are preparing a recommendation which will be submitted to President Eisenhower, who will make the final decision. Mr. Flemming said there is no jurisdictional or bureaucratic dispute involved.

VETERANS ADMINISTRATION FUNDS BOOSTED

House lawmakers overrode a House Appropriations Committee budget slash and voted the Veterans Administration enough money to carry out slight fee increases for certain outpatient care by private physicians.

The committee had chopped the outpatient care budget request by $866,000 to a total of 83 million dollars, a cut that would have imperiled the proposed increase in private fees. However, the House restored the amount cut.

In sending the money measure to the Senate the House also approved more money than allowed by the committee for VA inpatient care and for general operating expenses. A total of $792,100,000 was granted for inpatient care at VA hospitals, $14,600,000 more than the committee allotted and 5 million dollars more than the administration sought. General operating expenses were raised $3,400,000 over the committee figure, to $163,400,000.

All told, the agency received $9,500,000 more than the administration sought for the fiscal year starting July 1. The total was $5,039,000,000.

In okaying $30,159,000 for VA hospital construction, an increase of 10 million dollars over the budget estimate, the Appropriations Committee said that for several years it has "urged the Veterans Administration to accelerate its modernization and replacement program, and the increase in the bill will enable VA to move significantly ahead."

The bill provided $15,300,000 for VA medical research, compared with the 11 million dollars proposed by the administration.

HOUSE SLASHES CIVIL DEFENSE MONEY REQUEST

The administration's budget recommendation for the Office of Civil and Defense Mobilization was severely cut by the House, which voted heavy reductions in funds for federal stockpiling of emergency supplies and for allocations to the states. The 25 million dollars recommended for federal financial assistance to the states was pared to 10 million dollars; the $13,900,000 for stockpiling was cut in half. Of the over-all $70,100,000 asked by the administration for the agency, the House approved only $43,700,000.

In another economy move the House trimmed the request of the National Science Foundation from the $160,300,000 asked to a total of $143,200,000.

INTERNATIONAL HEALTH PROGRAMS BACKED

Lawmakers, physicians, health leaders, and businessmen agreed on the need for expanded efforts to tackle international health problems at the second National Conference on World Health held in Washington, D. C., recently. Much of the discussion at the conference, sponsored by the National Citizens Committee for the World Health Organization, centered on the measure approved by the Senate Labor and Public Welfare Committee that would create a new National Institute of International Medical Research. Sen. Lister Hill (D., Ala.) chairman of the committee, predicted Congress would approve the bill and that 50 million dollars would be appropriated for the program's operations next fiscal year. All of the speakers at the three-day conference agreed that the federal project should not hamper private efforts.

During one of the panel discussions it was disclosed by Dr. James A. Shannon, director of the National Institutes of Health, that the measure may be modified to authorize use of funds abroad for public health research programs as well as for medical research.

MISCELLANY

U. S. Surgeon General Leroy Burney warned that a recent outbreak of smallpox in Germany points up the need for all Americans to be vaccinated against the disease. Persons traveling abroad should get up-to-date shots, he said. The official disclosed that as a result of the epidemic in Germany that cost two lives, 15,000 Germans entering the United States were screened by the U. S. Quarantine Service. The German outbreak was introduced in that country by a physician who had contracted the disease in India.

The Food and Drug Administration is investigating reheated fats, such as some of those used in making potato chips, to determine whether breakdown products might be toxic. The inquiry was prompted when a fat by-product used in feeds caused chicken disease some months ago.

IN THREATENED OR HABITUAL ABORTION... MORE FULL TERM PREGNANCIES...

ENOVID®

... SIMULATES CORPUS LUTEUM HORMONES, thereby
... SUPPORTS THE ENDOMETRIUM, hence
... SUSTAINS FETAL LIFE

Enovid, through its pronounced progesterone-like action and its lesser estrogenic action, enhanced by the addition of ethynylestradiol 3-methyl ether, mimics the action of the corpus luteum hormones.

In *threatened abortion,* due to an endocrine failure to support the hypertrophied endometrium of pregnancy, the potent progesterone-like activity of Enovid is of value.

In *habitual abortion,* resulting from inadequate corpus luteum activity, Enovid supports the decidual endometrium and therefore encourages continuation of the pregnancy.

Each 10-mg. tablet of Enovid contains 9.85 mg. of norethynodrel, a new synthetic steroid, and 0.15 mg. of ethynylestradiol 3-methyl ether.

DOSAGE IN THREATENED ABORTION

Two or three tablets daily on appearance of symptoms. This dosage may be reduced to one or two tablets daily when symptoms disappear. The reduced dosage should be continued to term and an increased dose given if symptoms reappear.

DOSAGE IN HABITUAL ABORTION

One or two tablets daily as soon as pregnancy is diagnosed and continued without interruption at least through the fifth month. Enovid may be safely continued to term if desired.

ENOVID Oral Synthetic Endometropin
(brand of norethynodrel with ethynylestradiol 3-methyl ether)

THE PROBLEM OF MALIGNANCY IN NODULAR GOITER—RECAPITULATION AND A CHALLENGE

Joseph E. Sokal, M.D., Buffalo

The relation of thyroid cancer to nontoxic nodular goiter and to initially benign thyroid adenomas has been the subject of prolonged and vehement controversy. Some authors have claimed that very many nontoxic nodular goiters are malignant and have recommended immediate thyroidectomy in all cases. It is here pointed out that nontoxic nodular goiter is a fairly common finding (at least 30,000 palpable goiters per million of population) while thyroid cancer is rare (only 25 cases diagnosed per million of population per year). There is evidence that surgical removal of all nodular goiters would result in more loss of life than could be justified by the resultant decrease in mortality from thyroid cancer. Emphasis today should be on the differential diagnosis of the thyroid nodule, with prompt operation in cases where the probability of malignancy is high and conservative treatment otherwise.

THE ASSOCIATION between nodular goiter and thyroid cancer was first commented on many years ago. Thyroid cancer was known to be more common in regions where goiter was prevalent than in "nongoitrous" areas. Leading authorities taught that the majority of thyroid cancers arose in previously benign adenomas. However, there was not much concern over the risk of cancer in the individual patient with nodular goiter. In 1929, for example, Coller[1] wrote:

> The ratio of carcinoma to goiters removed varies with the clinic from 1.2 to 4.6 per cent, but this gives an exaggerated idea of the adenoma as a precancerous lesion. As Balfour pointed out, patients with cancer of the thyroid eventually seek surgical aid, while the majority of persons with adenomatous goiters are not operated on. The true incidence of carcinoma in adenoma cannot be stated, but it would be very much less than any figures we have at present. The adenoma is a precancerous lesion but the true incidence is so small that it should not be a great cause for anxiety to the person with adenomatous goiter.

In 1945, however, this view was strongly challenged by Cole, Slaughter, and Rossiter,[2] who stated that a high percentage of nontoxic nodular goiters are malignant. Since then literally hundreds of papers have been written on this subject, and discussion of the problem has often been marked by violent controversy. Some authors have claimed that very many nontoxic nodular goiters are malignant and have recommended immediate thyroidectomy in all cases. Others feel that the incidence of malignancy in nodular goiter is quite low, that only a few selected cases should be

operated on, and that even in these cases moderate delay in treatment has relatively little effect on the final outcome. In spite of the extensive literature on this subject, no agreement appears to have been reached regarding the basic statistics or the preferred management of patients with nodular goiter. It is the purpose of this paper to review this problem, summarize the opposing viewpoints, call attention to additional statistical evidence which is now available, and indicate the kinds of information needed to resolve the present controversy.

Arguments for Routine Removal of Nodular Goiters

By far the majority of publications on this subject support the view that the incidence of malignancy among nontoxic nodular goiters is quite high and that most or all such goiters should be removed as soon as they are detected, because of the risk of cancer. It has been claimed that many lives could be saved by systematic search for, and removal of, nodular goiters. This doctrine, which is taught to most medical students and surgical residents today, is based on the following considerations:

Statistics from many surgical centers throughout the United States indicate that from 4 to 17% of all nontoxic nodular goiters removed are malignant.

The reports dealing with this subject are too numerous to discuss individually. Some authors reporting very high percentages of malignancy have included patients known preoperatively to have thyroid cancer under the heading of "nontoxic nodular goiter." This practice is undesirable and tends to confuse the issue. The question under discussion is, "How many nodular goiters are malignant?" not, "How many thyroid cancers are malignant?" When the two groups are combined in varying proportions, statistical evaluation becomes impossible. Fortunately, many authors guilty of this practice provide sufficient information to make it possible to exclude the known cancers and recalculate the necessary percentages. When this is done, the percentage of malignant goiters is reduced somewhat and agreement with other reports is better. One may conclude that approximately 8% of nontoxic nodular goiters removed at representative surgical centers in the United States are malignant.

It is impossible to differentiate preoperatively between benign and malignant goiters.

This statement is made by most authors discussing this problem. In some cases it is supported only by a few case histories of patients thought to have benign goiter who proved to have thyroid cancer. In most reports, however, the preoperative classification of patients is given in evidence. Cases are divided into "cancer suspected" and "cancer unsuspected" groups. As would be expected, malignancy is found more frequently in the former than in the latter. However, even among the nontoxic nodular goiters removed without the preoperative recording of a suspicion of cancer, histological examination demonstrates malignancy in a significant number. There is rather good agreement among most authors that the frequency of malignancy in this "cancer unsuspected" operative group ranges from 3 to 7%. This category includes by far the majority of patients and the majority of thyroid cancers, in most recent series. It is concluded, therefore, that preoperative differentiation between benign and malignant goiters is impossible in most cases. Furthermore, many of the criteria on which the clinical impression of thyroid cancer is based, such as fixation, tracheal compression, and vocal cord paralysis, are associated with poor prognosis. It would be unfortunate if surgery were delayed until such signs develop.

Even though a nodular goiter may be benign at the time it is detected, it is likely to become malignant later and should therefore be removed as cancer prophylaxis.

Many authors have emphasized this point. They cite the fact that in many series of thyroid cancers a history of preexistent goiter, often of long duration, was elicited in a large percentage of patients. Some authors cite individual case histories of patients with quiescent, apparently benign nodular goiters which eventually began to grow rapidly and proved to be thyroid cancer. Lahey and Hare[3] stated, "Prophylactic removal of all discrete adenomas would do much to lower, if not abolish, the occurrence of cancer of the thyroid." However, no author recommending prophylactic thyroidectomy has presented evidence to indicate just how frequently benign goiters become malignant. Some, in fact, have minimized this argument and base their recommendation for routine removal of nodular goiters on the thesis that thyroid nodules are likely to be malignant rather than become malignant.

The operative mortality and morbidity in nontoxic nodular goiter is so small as to be insignificant. Therefore, it is worthwhile to operate on 100 patients even if only 3 or 4 prove to have thyroid cancer.

It has been pointed out that more cancers are found at thyroidectomy for nontoxic nodular goiter than at biopsy of clinically benign breast masses.[4] Since the latter is accepted as a routine procedure, the former should be also. Additional advantages of thyroidectomy which are emphasized include the relief of pressure symptoms, the cosmetic benefits, and the relief of anxiety over possible malignancy on the part of both the patient and the doctor.

Arguments Against the Routine Removal of Nodular Goiters

Several authors have voiced strong objections to the thesis that all nontoxic nodular goiters should be removed as soon as they are found. They present the following arguments:

The statistics reported from surgical centers are highly selected and are not representative of the population in general.

The great majority of patients with nodular goiter are never seen by surgeons and thus do not appear in surgical statistics. Patients often refuse surgical referral, in the conviction that a goiter which has been static and asymptomatic for years need not be removed. General practitioners and internists refer asymptomatic patients to surgeons chiefly when they are concerned over the possibility of cancer (whether or not they record such suspicion in the clinical record). Many nodular goiters regress with iodine or thyroid medication, or spontaneously, and thus do not appear in surgical statistics. Thus, only a minority of nontoxic nodular goiters are operated on; these have been carefully selected at nonsurgical levels, with elimination of most of the benign cases. The surgeons see, and operate on, a small group which contains most of the thyroid cancers. The percentage of cancer reported by surgeons is simply a reflection of the efficiency of the preoperative selective process. If less preoperative selection took place, the incidence of malignancy among surgical specimens would be lower than the usual 8%. In one series with relatively little selection, cancer was found in 1.7% of nodular goiters.[5]

Nodular goiter is quite common, while thyroid cancer is very rare. Therefore, only a small percentage of nodular goiters could possibly be malignant.

Estimates of the frequency of nontoxic nodular goiter in various regions of the United States have been made. The population samples examined varied considerably. Results range from 3 to 4%, detected during physical examination of healthy adults in a "nongoitrous" community,[6] to 57%, found on sectioning of thyroid glands at autopsy, in an area having a high incidence of endemic goiter.[7] Even the lowest of these estimates indicates that several million people in this country have nodular goiter. On the other hand, the frequency of thyroid cancer is very low. The annual incidence of thyroid cancer in the United States is about 25 per million population.[8] Recorded deaths from thyroid cancer number about 1,000 per year in the entire United States, according to the National Office of Vital Statistics. It is obvious, therefore, that only a very small percentage of nodular goiters could be malignant.

Benign goiters can be distinguished clinically from possibly malignant ones with considerable accuracy.

This statement is supported by several lines of argument. The fact that malignancy is found in about 8% of surgical specimens, while statistical calculations indicate that considerably fewer than 1% of all nontoxic nodular goiters could possibly be malignant (see above), is prima facie evidence of rather efficient selection for surgery. There are objections to this simple "proof" of selection, however, which will be discussed below. More acceptable is the evidence presented by authors such as Crile and Dempsey[9] and myself[10] that a relatively large number of cancers were found among nontoxic nodular goiters initially selected for surgical treatment, while few or no cancers were found on follow-up of cases where surgery was not initially recommended. Finally, it has been pointed out by several authors that the thyroid gland is very favorably situated for clinical examination and that a skilled examiner can readily decide whether nodules are likely to be malignant or benign, without waiting for such frank signs of advanced cancer as vocal cord paralysis. Hard, irregular masses with indistinct margins, which grow progressively, are certainly suspect. On the other hand, round, smooth, soft or cystic, sharply defined nodules, which do not grow, may be left alone. Important factors in reaching a clinical decision are reexamination of the thyroid on several occasions over a few months and observation of the effect of thyroid medication on the size of the goiter. Most benign nodules become smaller or disappear with such medication.[11] Radioactive iodine–uptake studies may also be of assistance in differentiating between benign and malignant nodules.[12]

Benign goiters very rarely undergo malignant transformation; hence prophylactic thyroidectomy is not indicated. Furthermore, there is no assurance that prophylactic partial thyroidectomy will prevent the development of thyroid cancer.

Some statistics are now available on the follow-up of groups of patients with apparently benign nontoxic nodular goiter.[13] The development of thyroid cancer among such patients is a very rare event. The principal criticism of some reports of this sort is that the follow-up period may be too short.

The efficacy of prophylactic thyroidectomy is challenged by the presentation of case histories in which thyroid cancer was found some years after the removal of benign nodular goiters. Such cases are not particularly unusual; in one series of thyroid cancer, 17% of patients had had previous thyroidectomy for benign goiter.[14]

Moderate delay in surgical treatment does not appreciably change the outcome of thyroid cancer.

Most authorities agree that thyroid cancers may be classified into two broad groups, according to biological behavior. One, accounting for perhaps one-third of the cases and including several histological types, grows rapidly and invades early and is usually not cured even when immediate surgery is performed. The other, accounting for the majority of cases (principally, papillary adenocarcinoma), grows slowly, is relatively noninvasive, metastasizes late, and has a high "cure rate" even when surgery has been long delayed. Hence, a period of three to four months of observation, prior to reaching a final decision regarding surgery, is justifiable. During this period, the criteria for malignancy or nonmalignancy can be reevaluated and the effect of thyroid or iodine medication can be studied.

Some Statistical Considerations

Frequency of Nodular Goiter and Thyroid Cancer.—An upper limit for the frequency of malignancy among nontoxic nodular goiters can be calculated by comparing the number of such goiters to the number of thyroid cancers in the population. Obviously, if in a particular community there are 1,000 people with nodular goiter and 20 with thyroid cancer, the incidence of malignancy among the nodular goiters cannot be greater than 2%. It may be less than this, however. If five of the thyroid cancers did not present as nodular goiters, for example, the incidence of malignancy among nodular goiters would be only 1.5%. Thus, if we can estimate the frequency of nodular goiter and of thyroid cancer in the United States, we can calculate the maximum possible incidence of malignancy in nodular goiter. The actual figure will be lower than this, since it is known that some thyroid cancers do not arise in nodular goiter and do not present as palpable thyroid nodules. Others are obviously cancer when first seen and would not be counted among nodular goiters.

Several years ago, I made some estimates of the prevalence of nodular goiter and of thyroid cancer in the United States and attempted such calculations of the frequency of malignancy among nontoxic nodular goiters. The basic data I used were not as complete and as accurate as the statistics now available, and my results were, in part, based on indirect calculations. In the light of the better information now available, it is possible to calculate the desired figures more accurately.

The prevalence of nodular goiter differs in different parts of the country and varies with sex and age. It is higher among women than men, in the older age groups than in young adulthood, and in the Great Lakes and Pacific Coast regions than in the East or South. Not all thyroid nodules are clinically detectable; autopsy studies regularly show a higher incidence of nodular goiter than do clinical surveys. Since the problem under discussion is a clinical one, the desired figure is that giving the percentage of clinically palpable nodular goiters in our population. In order for this figure to be representative of the entire population, it should be based on surveys of apparently well individuals, rather than on hospitalized groups, where the incidence of all types of abnormalities might be higher.

The best study of the prevalence of nodular goiter in a representative population sample is that reported by Vander, Gaston, and Dawber.[6] These authors examined over 5,000 individuals between the ages of 30 and 60 in a Massachusetts community. This sample constituted over half of the total population of the community in this age group. Thyroid nodules were felt by one or more examiners in 4% of this group. Individuals under 30 years of age were excluded from Vander's study. This age group, with a low incidence of nodular goiter, outweighs the smaller group over 60 years of age, also excluded, where thyroid nodules are more common. Thus the prevalence of palpable nodular goiter in the entire population of the community sampled by Vander is probably about 3%, rather than 4%. Statistics of comparable quality are not available for other regions of the country. However, such data as are available would suggest that the average for the United States as a whole is higher than that for the eastern seaboard. A very conservative estimate of the prevalence of clinically detectable nodular goiter in the United States as a whole would thus be 3 to 4%, or 30,000 to 40,000 per million population.

A highly accurate figure for the incidence of thyroid cancer in the United States has recently been presented by Mustacchi and Cutler.[8] It is based on a careful survey of 10 metropolitan areas in different regions of the country, with a combined population of 14,600,000. On the average, 25 thyroid cancers are diagnosed annually per million population. This is less than 1 case per 1,000 individuals with nodular goiter.

Comparison of the number of thyroid cancers diagnosed per year with the total number of nodular goiters in the community is a somewhat improper, though striking, way to present these statistics. It does, however, indicate the maximal annual risk for the individual with nodular goiter. This is small indeed. A better way of expressing this hazard is in terms of cumulative risk over a period of years, or over a lifetime. The cumulative incidence of thyroid cancer over an average lifetime of 65 years, calculated from Mustacchi's data, is 1,500 per million population. No good data are available for calculating the cumulative lifetime incidence of nodular goiter. This, of course, would be considerably higher than the prevalence in an average population at one time, given above. It cannot be much less than the 10% estimate I have made in the past, or about 100,000 per million population. Thus, among a million representative inhabitants of the United States, 100,000 would have nodular goiter at some time during their lives and 1,500 would develop thyroid cancer. Since not all thyroid cancers develop in preexistent goiter, the total lifetime risk for an individual with nontoxic nodular goiter cannot be much more than 1%.

Accuracy of Preoperative Evaluation of Nodular Goiters.—Whether it is possible to differentiate preoperatively between benign and possibly malignant goiters has been heatedly debated. The statistical proof of preoperative selection of thyroid cancers, referred to above, does not constitute a satisfactory answer to this question. Even if preoperative diagnosis were impossible, such statistical selection would still be observed, since thyroid cancers eventually come to surgery while most benign goiters do not. On the other hand, reports that "unsuspected" cancers were found in 3 to 7% of thyroidectomies do not constitute satisfactory evidence either. After all, there must have been some reason for referring these patients to surgery. On reviewing clinical charts in a leading university hospital, I encountered many cases in which small asymptomatic nodular goiters were removed without any indication that malignancy was suspected.[10] However, no other indication for surgery could be found on careful review of these charts. Other, apparently similar, cases were not referred for surgery. I was forced to the conclusion that physicians are often reluctant to record their suspicions of cancer in hospital charts.

Surgical statistics from representative university hospitals indicate that about 200 to 500 thyroidectomies for nontoxic nodular goiter are performed annually per million population. This represents only a fraction of the new nodular goiters arising in the community. If preoperative selection of possibly malignant goiters is impossible, then the great majority of thyroid cancers should not reach surgery until they are in an advanced stage, with malignancy clinically obvious. Survival rates should be poor. However, the opposite is the case. The majority of thyroid cancers are resectable, and current survival rates for thyroid cancer are better than for most other neoplasms. The majority of surgical failures are accounted for by the more rapidly invasive lesions, which usually come to operation promptly. Thus, preoperative selection of nodular goiter cannot be random from the standpoint of malignancy, whether or not suspicion of cancer is recorded.

Some degree of preoperative differentiation between benign and malignant goiters is therefore not only possible but actually occurring. In order to evaluate how accurately this can be done, individual series must be analyzed and the initial decision regarding surgery evaluated. Patients not operated on must be followed over a sufficiently long period of time to permit a decision as to whether cancer was originally present. In view of the slow progression of some thyroid cancers, a 10-year follow-up would be preferable to a 5-year one. Although follow-up reports on patients with nodular goiter not operated on have been given by several authors, the period of observation in most cases was not long enough to permit definitive conclusions to be drawn. In the small series I reported,[10] where follow-up was more adequate, highly accurate preoperative selection was demonstrated. Until additional studies are reported, however, an unqualified statement about the accuracy of preoperative selection cannot be made.

Uninodular Versus Multinodular Goiters.—Many authorities believe that malignancy is significantly more common among solitary thyroid nodules than in multinodular goiter. Lahey and Hare,[3] the principal proponents of this view, found thyroid cancer in 10% of uninodular but only 0.6% of multinodular goiters. No other author has reported such a striking difference, and some report no difference. On the average, cancer is found perhaps twice as often among uninodular glands as among those with multiple nodules. In some cases, this may be due to destruction of other preexistent benign nodules by a cancer infiltrating the thyroid gland. In any case, the clinical value of this distinction is dubious. Most nodular goiters are thought to be uninodular clinically.[15] However, at surgery or autopsy most prove to be multinodular. The number of thyroidectomies required to remove all apparently uninodular goiters would not be very much less than the number required to remove all nodular goiters, both uninodular and multinodular. Many authorities have therefore abandoned the attempt to differentiate between patients with uninodular and those with multinodular glands.[16]

Follow-up of Patients with Nodular Goiter.—The present controversy over nodular goiter could be conclusively resolved if statistics were available on the fate of a satisfactory unbiased sample of individuals with nodular goiter. Almost all of the statistics so far presented on this subject are based on selected groups of patients who are not representative of the populations of their respective communities. Patients referred for thyroidectomy constitute a biased sample which contains an excess number of malignant goiters. Patients examined and not referred for thyroidectomy also constitute a biased sample, containing an excess of benign goiters. Only by choosing a representative population sample through criteria not involving the thyroid, and then identifying all the individuals in that sample with nontoxic nodular goiter, can a valid study group be obtained. Follow-up of such a group for a sufficiently long period of time would provide direct answers to the questions presently in dispute: the true incidence of malignancy among nontoxic nodular goiters, the frequency with which benign goiters become malignant, and the accuracy of preoperative evaluation of nodular goiters.

The study of Vander, Gaston, and Dawber[6] is the only one so far reported which meets the above criteria. The preliminary report of these authors, presenting a five-year follow-up of 218 apparently healthy individuals with nontoxic nodular goiter, was published in 1954. Dr. John B. Vander[17] of the U. S. Public Health Service has very kindly furnished the following additional information on this group, now followed for 10 years: Twelve members of the group are now dead (coronary occlusion, seven, and cerebral vascular accident, carcinoma of kidney, carcinoma of cecum, carcinoma of liver, and carcinoma of lung, one each). No member of the group has as yet developed evidence of thyroid cancer.

Although 218 individuals do not constitute a very large sample, and 10 years is not a definitive follow-up period, these findings are highly significant. It is very unlikely that any thyroid cancers originally present in this group would not by now have become evident. If 8% of nontoxic nodular goiters are malignant, 17 thyroid cancers should have appeared in this group. The probability that no thyroid cancer would occur in a sample of this size, drawn from a very large hypothetical population with an 8% frequency of thyroid cancer, is 0.0000001. The probability that such a sample would be drawn from a population with a 4% frequency of thyroid cancer is 0.00013. This constitutes very strong evidence that the true frequency of malignancy among nodular goiters is much less than 8%, or than 4%. On the other hand, statistical evaluation supports the hypothesis that the correct figure is less than 1% (89% probability). Thus, the direct evidence on this point confirms the indirect calculations presented above.

Similarly, adequate follow-up information on patients with nodular goiters not operated on can provide direct evidence regarding the frequency with which benign nodular goiters become malignant. Here, selection of a study group is simpler. All that is necessary is to identify a group of individuals with benign goiters at some arbitrary point in time and follow their fate. Cases in which thyroid cancer becomes evident within a relatively short period (e. g., six months for anaplastic carcinoma, two years for papillary adenocarcinoma) should be excluded, since such would probably have been malignant at the start of the study. A 10-to-20-year follow-up of all other cases would provide the desired information with satisfactory accuracy; even a 5-to-10-year follow-up would provide useful data. Such a study could be performed retrospectively, if an unbiased method is available for identifying patients known to have had nontoxic nodular goiter at an appropriate time in the past. The limited direct evidence of this type so far available, as well as my indirect calculations,[10] indicate that malignant transformation of benign nodular goiters is very rare.

Again, the prospective or retrospective follow-up of a suitable group of patients with nontoxic nodular goiter would provide information on the efficiency of preoperative identification of malignant goiters. Some members of such a group of patients will undergo thyroidectomy promptly after their goiters are discovered. Others will be operated on at some later time. A few might die of inoperable thyroid cancer. By comparing the frequency of curable and incurable thyroid cancers among the patients promptly referred to surgery with the frequency of such cancers in the group where surgery was delayed, an evaluation of preoperative selection can be made.

Comment

Incidence of Thyroid Cancer.—The opposing camps are in agreement on only one point, that nontoxic nodular goiter is a fairly common finding. I know of no one who has criticized my estimate of the frequency of nodular goiter as too high; many would say it is too low.[18] There was some disagreement in the past over the incidence of thyroid cancer. More recently, however, review of all types of statistics on thyroid cancer showed them to be in satisfactory agreement. The figures presented by Mustacchi and Cutler[8] are based on an extremely thorough survey of a large sample of the entire population of the United States. An incidence of thyroid cancer of 25 cases per million population per year is as close to the final verdict as epidemiologic techniques can give.

We are all agreed that there are at least 30,000 to 40,000 individuals with nodular goiter per million of population. If 8% of all nodular goiters are malignant, then there must be 3,000 cases of thyroid cancer per million population. However, only 25 are diagnosed per year. Where are the others? They are not being cured, for they do not appear in surgical statistics.[19] Nor are the patients dying, for the cases do not appear among death certificates or on the autopsy table. Clearly, the burden of proof must now rest on those who claim that such large numbers exist at all.

The evidence for a highly efficient preoperative selective process appears unassailable. Where careful preoperative selection is practiced, the incidence of cancer among nodular goiters removed may be as high as 17%.[12] Where less selection occurs, it may be one-tenth of this figure.[5] Surgeons are usually not aware of the extent of preoperative selection, since it is accomplished principally by patients, general practitioners, and internists. In discussions of this problem with general practitioners, I have frequently been told, "I have followed quite a few patients with nodular goiter for years. I have never seen a thyroid cancer in my practice." It is unfortunate that the combined experience of a group of general practitioners has never appeared in the literature of this subject.

A Challenge:—There are, at the very least, 5 million people in the United States with palpable nontoxic nodular goiter. If as many as 8% of these goiters are malignant, there must be over 400,000 thyroid cancers in the United States. Nodular goiter is not a new disease, so it cannot be claimed that these hypothetical cancers have not yet become evident. If so many cases of thyroid cancer exist, it should be possible to find them. Let those who claim that they exist survey a suitable population sample and show us the necessary number of people either dying or being cured of thyroid cancer.

Differentiation of Benign from Malignant Goiters.—The evidence so far available indicates that very few benign nodular goiters become malignant. In several series, totaling about 6,000 patient-years of observation, no thyroid cancers were observed to develop among presumably benign nodular goiters. The study of Vander, Gaston, and Dawber[9] is a particularly important one in this regard, *since it* represents a carefully organized prospective study of a relatively large and representative sample of a healthy population. Future reports from these workers should provide a definitive answer on this point.

Probably the most important, and certainly one of the most hotly debated, points in the controversy over nodular goiters is the question, "Can benign goiters be differentiated preoperatively from possibly malignant ones?" Plausible arguments have been presented by both sides. Here, the proof of the pudding must be in the eating. If a relatively large number of nodular goiters referred for surgical extirpation contain cancer (as they do), and very few goiters not so referred prove to be malignant (as appears to be the case), then preoperative differentiation is being successfully practiced, whether or not cancer suspicion is recorded in patients' charts.

A Challenge:—A prospective study of the efficiency of preoperative selection in nontoxic nodular goiter would take years to complete. Furthermore, a physician who sincerely believes that it is impossible to differentiate between benign and malignant goiters cannot be expected to violate his conscience by deferring surgery on one group of patients with nodular goiter. However, there is another way to answer this question. Every community has large numbers of people who have had nodular goiter for years. By careful searching of physicians' records and hospital files, it should be possible to identify patients who have had nodular goiter described as an incidental finding many years ago and who were not referred for surgery. (In most institutions it will be necessary to review individual charts, since such "incidental" goiters usually will not appear in a record room diagnostic index.) Let those who believe preoperative selection impossible search for patients recorded as having nodular goiter 10 to 20 years ago, trace these patients, and determine the incidence of thyroid cancer (which should now be obvious) among those not subjected to thyroidectomy. Let them compare this with the corresponding figure for the patients treated surgically. There is no need for concern about whether cancer was suspected or not; in the great majority of cases where cancer was seriously suspected, one may assume that operation followed. Let them simply compare, as I did, the frequency of thyroid cancer among cases where operation was not performed with its frequency among the cases referred for surgery. If preoperative selection is truly impossible, the figures will be identical. They should exclude all patients in the operative group who had palliative resections and, if they wish, all patients who died of thyroid cancer within five years of surgery. Then their figures will certainly measure preoperative selection of "early" cancers.

Conclusions

A generation ago, a large percentage of thyroid cancers were being diagnosed at an advanced and incurable stage. Today, the majority are being diagnosed early and patients are being cured. A major share of the credit for this improvement belongs to the physicians who have called our attention to the potential hazards of the thyroid nodule. As a result of their publications, we are all more aware of the fact that apparently innocent nodular goiter may in fact be thyroid cancer. Patients with suspicious goiters are now being operated on early enough to cure most of the patients with malignant ones. Without question, this is a major advance in cancer therapy. However, as with many reforms, the pendulum has swung too far. *The doctrine that all nodular goiters must be extirpated as soon as they are detected is just as fallacious as the attitude that thyroid cancer is an unimportant cause of death and that masses in the thyroid may be ignored.*

The mortality and morbidity of thyroidectomy are low. However, they are not zero. As several authors have pointed out, the removal of all nodular goiters would certainly result in more loss of life than could be justified by the resultant decrease in mortality from thyroid cancer. It is clear that our efforts should be directed toward improvement of *the criteria for selection of patients for* surgery, rather than toward detection and extirpation of all thyroid nodules.

PULMONARY INFARCTION AFTER DENTAL EXTRACTION

REPORT OF TWO CASES WITH RECOVERY

Crawford W. Adams, M.D.
and
James M. Hudgins, M.D., Nashville, Tenn.

Two case-histories involving men aged 40 and 38 years illustrate the occurrence of pulmonary disease after extraction of teeth. In the first case the pulmonary symptoms commenced seven days after the extraction, with a sudden rise of temperature to 40 C on the 10th day marking the development of a pulmonary infarct. In the second case the pulmonary symptoms commenced five days after the extraction, and the subsequent course was marked by two episodes of severe chest pain indicating the development of pulmonary infarcts. Although the connection of the pulmonary symptoms with the dental procedures was not obvious at first, it became clear later that both patients had cervical phlebothrombosis which led to the pulmonary complications. It is concluded that in all cases of unexplained pulmonary infarction the patient's dental history should be considered.

Although dental extractions are probably the commonest cause of cervical trauma, they are rarely associated with cervical phlebothrombosis or pulmonary infarction. The neck veins usually involved with infection or trauma to the jaws are the ranine, facial, and internal jugular veins. Two patients with cervical phlebothrombosis and associated pulmonary infarction after dental extraction were observed, however, and their cases are reported.

Report of Cases

Case 1.—A 40-year-old man was admitted to the Mid-State Baptist Hospital on Oct. 3, 1956, with the complaint of chest pain associated with chills and fever of two weeks' duration. Three weeks prior to admission, because of abscess formation and advanced periodontoclasia, his two right upper molar teeth had been extracted after a local infiltration of lidocaine hydrochloride. Two days after the extractions the patient developed unusual pain in the right side of the neck, associated with slight swelling. Five days later the patient had pain in the right lower part of the chest, associated with an elevation of temperature. He was seen by his family physician and was told he had "pneumonia," which was treated with "antibiotics" for two weeks. The pain in the right side of the chest increased and then occurred in the

---

side. He had several "shaking" chills associated with a gh productive of clear sputum. On one occasion the tum was "streaked with blood." The day before adssion to the hospital a roentgenogram demonstrated an vation of the left dome of the diaphragm, thickening of e pleura, and a wedge of increased density in the left ver lung field. In the right lower lung field were two ear areas of atelectasis above the diaphragm (fig. 1*B*). roentgenogram made three years previously had revealed normal cardiac silhouette and clear lung fields (fig. 1*A*). The patient was an obese apprehensive male, lying comtably in bed without dyspnea or orthopnea. His blood essure was 130/90 mm. Hg, pulse 80 per minute, respiraons 20 per minute, and temperature 100.4 F (38 C). There as extensive periodontal disease, with ulceration of the terior gum margins and advanced caries of the right teral incisor and the second right lower molar tooth. There as slight swelling and tenderness to deep palpation along e right lateral aspect of the neck. The chest was symetrical and obese. Auscultation disclosed numerous moist spiratory rales over both lower lung fields posteriorly. The heart size was normal to percussion and the sounds were of good quality. The peripheral arterial pulsations were equal, and there was no evidence of tenderness, heat, or swelling by direct measurement of the lower extremities.

Pertinent laboratory data were as follows: white blood cell count, 9,300 per cubic millimeter with 68% polymorphonuclear leukocytes. The Venereal Disease Research Laboratory test for syphilis gave negative results. The corrected erythrocyte sedimentation rate (Wintrobe method) was 34 mm. in one hour. Sputum was negative for pathogens. A diagnostic thoracentesis of the left side of the chest was performed and no acid-fast bacilli or malignant cells were found. Result of tuberculin skin test was negative. The electrocardiogram was within the limits of normal.

The provisional diagnosis was "virus pneumonia." The patient was treated with aqueous penicillin, 600,000 units every 6 hours, and dihydrostreptomycin sulfate, 0.5 Gm. every 12 hours. A left anterior oblique roentgenogram eight days after admission to the hospital showed linear atelectasis in the right lower lung field and atelectasis associated with pneumonitis and pleural effusion at the left lung base (fig. 2*A*). Four days later a roentgenogram of the lower anterior teeth demonstrated generalized alveolar absorption and periapical and periodontal abscesses involving the mandibular central incisor and the left cuspid (fig. 3). Ten days after admission to the hospital the patient's temperature rose suddenly to 104 F (40 C) and a roentgenogram demonstrated another area of infiltration, typical of pulmonary infarction, at the left lung base.

After consultation the diagnosis of pulmonary emboli originating from a deep cervical vein phlebothrombosis was made. The patient was given bishydroxycoumarin, and the prothrombin time was maintained at a therapeutic level between 15 and 30% of normal. His daily temperature remained elevated, between 100 F (37.7 C) and 104 F, for 5 days and returned to normal on the 20th hospital day. Anticoagulant therapy was continued until the 28th hospital day. A roentgenogram of the chest on the 30th hospital day demonstrated essentially clear lung fields (fig. 2*B*). Surgical removal of the infected teeth was uncomplicated. The antibiotic therapy was maintained until the 32nd hospital day, at which time the patient was discharged. For the past two years there has been no further difficulty.

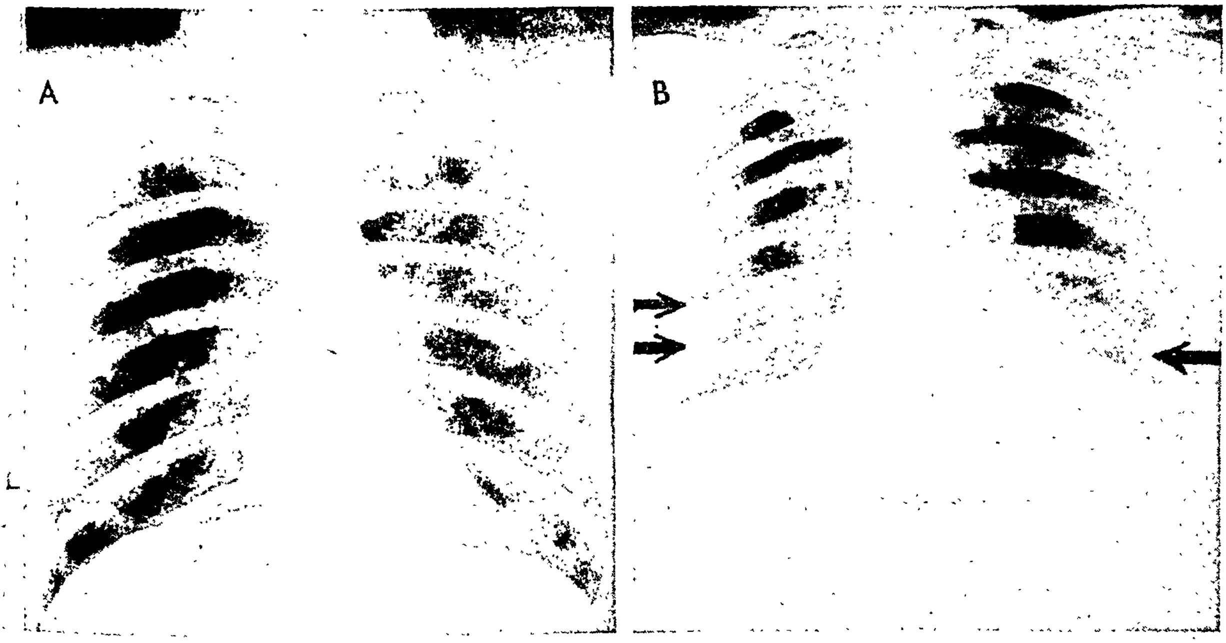

Fig. 1 (case 1).—*A*, normal roentgenograms of heart and lung fields made Sept. 21, 1953. *B*, roentgenogram made Oct. 3, 1956. *Arrows*, pleural thickening and wedge of increased density in left lower lung field and two linear areas of atelectasis above right side of diaphragm.

This case is of unusual interest because of the development of phlebothrombosis of the neck veins and subsequent pulmonary infarction two weeks after the extraction of infected teeth. Because oral infections may be a source of pulmonary embolization, careful examination of the teeth including roentgenograms should be made in all cases of unexplained pulmonary infarction. The development of a sudden pulmonary or pleural "infection" after dental extraction should alert the physician to the possibility of underlying phlebothrombosis of the cervical veins and pulmonary infarction.

Case 2.—A 38-year-old man was first seen by his family physician on June 5, 1958, complaining of "severe left chest pain" intensified by deep inspiration and associated with a nonproductive cough. Five days previously, after a local infiltration of lidocaine hydrochloride, two infected teeth had been extracted.

His temperature was 99 F (37.2 C). There were marked periodontal disease, swelling and tenderness along the anterior lateral aspect of the right side of the neck, and dulness to percussion and moist rales audible over the lower left lung field laterally and posteriorly. The extremities were without tenderness, heat, or swelling by direct measurement.

On the following day the pain in the left side of the chest became more severe, and a roentgenogram revealed small areas of infiltration suggestive of atelectasis in both lower lung fields. The patient was treated with tetracycline phosphate, 250 mg. every six hours, and there was slight improvement. One week later he had another episode of sudden sharp pain in the lower left chest region and again an area of linear atelectasis at the left lung base was demonstrated (fig. 4A). The white blood cell count was 14,800 per cubic millimeter, and the differential blood count unremarkable.

The patient was admitted to Mid-State Baptist Hospital on June 17, 1958, 12 days after the original onset of chest pain. He was given novobiocin sodium, 250 mg. every six hours, and bishydroxycoumarin. Roentgenograms of the teeth

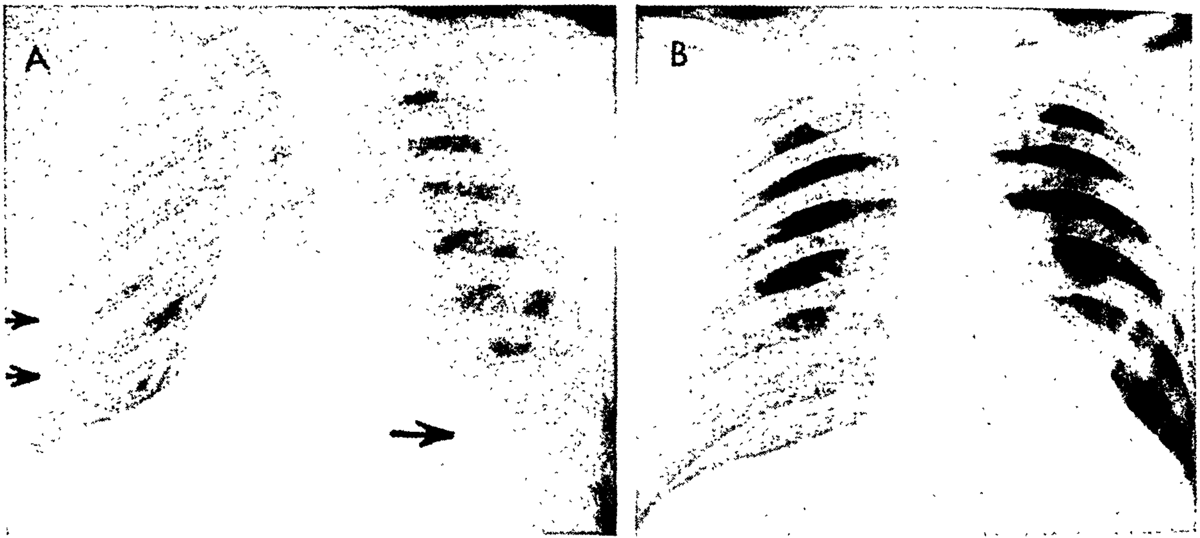

Fig. 2 (case 1).—*A*, eight days after admission to hospital, on Oct. 11, 1956, left anterior oblique roentgenogram demonstrated (*arrows*) linear atelectasis in right lower lung field and atelectasis with pneumonitis and pleural effusion at left lung base. *B*, 30 days after admission to hospital, on Nov. 2, 1956, lung fields were essentially clear.

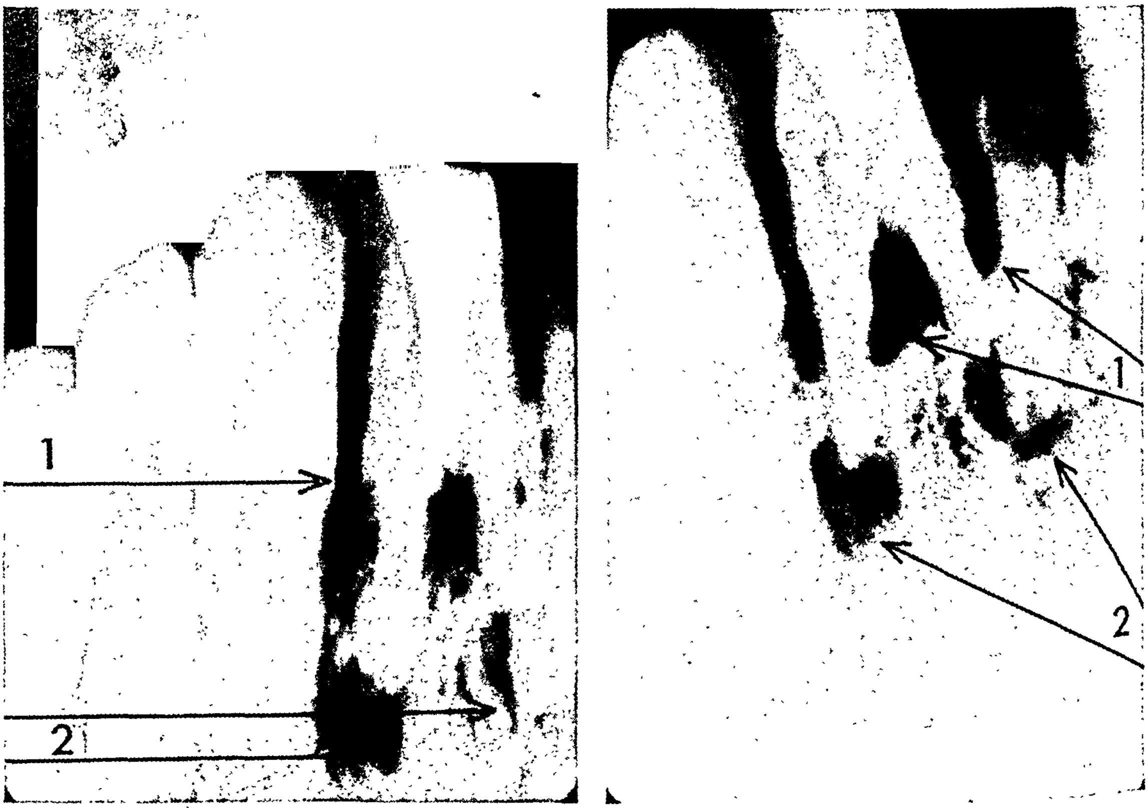

Fig. 3 (case 1).—*Left*, left cuspid. *Right*, central incisor. *1*, periodontal abscesses; *2*, periapical abscesses.

vealed far-advanced periodontal absorption. Bishydroxy-oumarin therapy was continued for 6 days, and on the 10th ospital day the patient had an uncomplicated full-mouth traction of the infected teeth. Novobiocin therapy was scontinued three days after surgery. A roentgenogram 30 ays after the onset of the illness showed no evidence of filtration or atelectasis (fig. 4*B*). The patient was dis-arged after 13 hospital days and for six months has been ithout symptoms.

Review of Literature

Swift,[1] who in 1940 reviewed 49 cases of neck infections collected between 1930 and 1940, was impressed by the unusual array of causal factors; however, neck infection after extraction of infected teeth was common. All but one of the patients with fatal cases of neck infection had teeth extracted before the onset of the neck infection, and local or block anesthesia was used in all of these cases. In Swift's review there were no cases of thrombophlebitis of the internal jugular veins.

In 1942 Iglauer[2] reported the case of a young woman with occurrence of thrombophlebitis of the left internal jugular vein after a sore throat of two weeks' duration who developed bacteremia with metastatic septic emboli to the shoulder, liver, and right lung with abscess formation. The patient recovered after nine surgical procedures and 133 days of hospitalization.

In 1947 Decker[3] pointed out that septic thrombophlebitis of the neck may result from an original focus of infection in the tonsils, ulcerated lesions of the oral cavity, dental abscesses, pharyngomaxillary abscesses, salivary gland abscesses, cellulitis of floor of mouth (Ludwig's angina), retropharyngeal abscesses, abscesses of the neck, or osteomyelitis of the mandible or maxilla.

Nathanson[4] in 1953 reported the case of a 62-year-old man who had an infected tooth removed from the right maxilla three days before the development of pain and swelling on the left side of the face. This left facial phlebitis and cellulitis developed as a result of a retrograde phlebitis of the right facial veins, caused by the septic tooth extraction. It can be seen that retrograde facial vein thrombophlebitis extending into the ophthalmic vein or the cavernous sinus after tooth extraction is not uncommon.[5]

Comment

The superior venous circulation is rarely considered a source of pulmonary infarction. Since there is often a delay of one or two weeks before the symptoms of embolization appear, it is not surprising that this disease of the lung is not associated with the earlier oral trauma. This suggests an important unrecognized cause of pulmonary disease.

The tendency of physicians to dismiss episodes of chest pain, fever, and cough as a "virus pneumonia" may allow this disease to go unrecognized. The ineffectiveness of antibiotics will only serve to confirm the erroneous diagnosis. An accurate diagnosis, based on recognition of the antecedent oral trauma, or a careful search for signs of cervical venous disease may be expected to reveal the correct etiology. This is more than an academic exercise, because proper treatment should include the early use of the anticoagulants.

Careful inspection of the neck region for swelling, tenderness, or other evidence of venous infection or obstruction should be undertaken, in

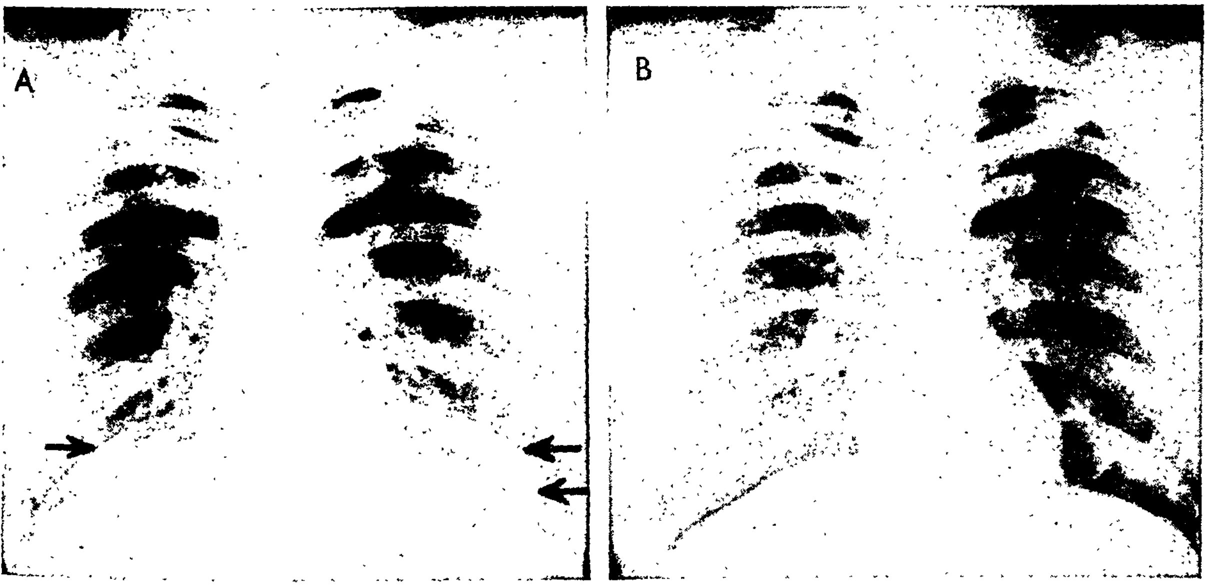

Fig. 4 (case 2).—*A*, chest roentgenogram made on June 19, 1958, demonstrated (*arrows*) linear atelectasis at both lung bases. *B*, on July 5, 1958, 30 days after onset of illness, roentgenogram demonstrated clear lung fields.

addition to routine examination of the lower extremities, with all episodes of unexplained pulmonary infarction.

Summary

Two instances of pulmonary infarction occurred after dental extraction and phlebothrombosis of the cervical veins. Both patients recovered. The superior as well as the inferior venous circulation should be carefully evaluated as a source of unexplained pulmonary infarction, and the distinction between pulmonary embolism arising from phlebothrombosis and "virus pneumonia" after dental extraction should be emphasized because of the importance of early recognition and treatment.

FILTRATION VERSUS LOCAL FORMATION OF LIPIDS IN PATHOGENESIS OF ATHEROSCLEROSIS

Russell L. Holman, M.D., Henry C. McGill Jr., M.D., Jack P. Strong, M.D.
and
Jack C. Geer, M.D., New Orleans

Efforts should be directed toward detection, concentration, and possible clinical utilization of active principles that govern lipid transportation and local accumulation. The best available evidence makes it seem likely that these active principles are enzyme-hormone complexes and indicates that active metabolic work is performed by the mesenchymal cells in the inner layers of the arterial wall. Much confusion can be avoided by keeping interspecies differences in mind and recognizing the probable stage of atherosclerosis in man at any given age. The three stages leading to clinical disease are fatty streaking in the first two decades, conversion of some fatty streaks to fibrous plaques in the second two decades, and local complications such as hemorrhage and thrombosis about a plaque in the third two decades.

The method whereby lipids accumulate in the inner layers of the arterial wall to constitute the first recognizable stage of atherosclerosis is one of the most cogent problems of our time. It is the purpose of this presentation to review the evidence for and against the two current hypotheses, filtration and local formation, and to discuss briefly the possible application of the findings to the pathogenesis of atherosclerosis.

Filtration

The data for filtration are based on logic and have no direct support. The argument can be stated simply. Too much of something in the diet leads to too much of something in the blood, and this in turn leads to too much of something in the arterial wall. This philosophy pervades much of the current literature about the relationship of dietary fats to atherosclerosis and implies that filtration is the mechanism whereby visible lipids make their appearance in the inner layers of the arterial wall.

From the Department of Pathology, Louisiana State University School of Medicine.

Read before the Section on Pathology and Physiology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

There is some inferential support for this argument in the work of Kellner and Chang [1] and others who found that labeled cholesterol appeared in the subcutaneous lymph of rabbits after intravenous injections or feeding. This tells us that the labeled compound can pass capillary endothelium, but nowhere has visible lipid been demonstrated and it is unwise to assume that endothelium in the turbulent environment of the aorta and large coronary arteries behaves the same as that in the quiet recesses of the capillary bed. One direct attempt to come to grips with the problem has been made by Buck,[2] who studied the inner surface of the endothelial cells of the aorta in rabbits and found that cholesterol feeding resulted in the production of large cisternae in the endoplasmic reticulum of the endothelial cells. This material was not osmiophilic, and it is questionable whether it was truly intracytoplasmic.

There is no doubt that the building stones for the lipids are filtered through the endothelium of the arterial wall and of the vasa vasorum and that elevations of blood pressure probably increase the rate of filtration, but the size, shape, form, and chemical structure of the effective building stones are not known. The bulk of evidence favors lipoprotein moieties, but passive movement of these moieties cannot account for the observation that visible lipid makes its first appearance in the cytoplasm of mesenchymal cells in the inner layers of the arterial wall.

The evidence against filtration is more or less conclusive. The size, shape, distribution, and general appearance of the early lesion cannot be explained on the basis of filtration (fig. 1). On the experimental side two masses of data are, to say the least, difficult to reconcile with concepts of filtration. The first of these has to do with the time interval between cholesterol feeding and the first appearance of lesions. Despite the fact that the blood cholesterol level and the level of the other blood lipids starts to rise within a few days after starting the cholesterol feeding, months must go by before lesions begin to make their appearance—and there is no strict correlation between the height of blood cholesterol level and the extent and degree of lesions. While, in general, it can be stated that some elevation of the blood cholesterol level is prerequisite for lesions, everyone who has worked with experimental animals has encountered some animals that do not get lesions, and the vast majority of humans with atherosclerotic lesions have no known hypercholesteremia or hyperlipemia. The other mass of data is even more damning to the filtration hypothesis. There are several examples of hypercholesteremia and hyperlipemia that have been dissociated from arterial lesions of any kind. Alloxan diabetes,[3] detergents,[4] and Seifter's lipid mobilizing factor [5] are all known to produce marked sustained hyperlipemia and hypercholesteremia with no ensuing arterial lesions of any kind. And the data that attempt to explain the absence of arterial lesions on the basis of cholesterol-phospholipid ratios leave much to be desired.

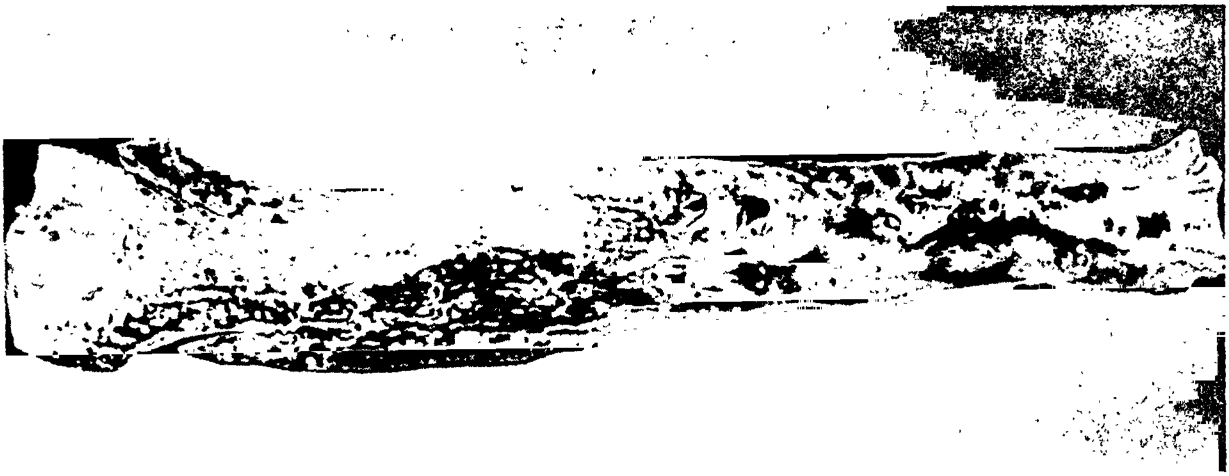

Fig. 1.—Section of aorta stained with Sudan IV. Fatty streaks and patches appear black. Size, shape, distribution, and appearance of lesions do not suggest filtration as method of local accumulation of lipid.

Local Formation

The evidence for local formation is derived from several sources and is increasing in quantity and quality. Siperstein and co-workers,[6] Werthessen and associates,[7] McCandless and Zilversmit,[8] and others have shown that labeled cholesterol and phospholipid can be recovered from the arterial wall within a period of a few hours after adding carbon-14 acetate or phosphorus-32 phosphate to the perfusion fluid in in vitro experiments or to the diet in in vivo experiments. Thus, there can be no question but that the mesenchymal cells in the arterial wall are capable of taking these simple building stones and fabricating lipids from them. Morphologic and histochemical studies on the calf aorta perfused with C^{14}-labeled acetate have confirmed the presence of intracellular and extracellular sudanophilic and osmiophilic lipid after an unexplained lag of about 48 hours.[9]

The gross appearance (size, shape, and distribution) of such lesions as are seen in figure 1 (from a 21-year-old man who died from malignant lymphoma) is admittedly difficult to explain by any mechanism but that of local formation. The curious patchy, speckled, and streaky lesions and sometimes even the serpentine distribution of the lesions, with varying degrees of elevation above the surface and varying amounts of lipid,[10] are no more difficult to explain than are the distribution, size, and shape of the areas and nodules of adenomatous hyperplasia in the thyroid, prostate, adrenal, breast, and ovary. All are compatible with the vagaries of end-organs in response to hormonal imbalance and are less confusing when viewed in the light of local affinities and proximities to source materials, i. e., of end-organs, which may be competing for priorities or may be imbalanced in many ways. Thus, it is possible to consider the mesenchymal cells in the arterial wall as target organs for hormones, and the size of these potential end-organs has been estimated.[11] The findings of Ingenito and associates[12] of a specialized cell in the myocardium and possibly in the intima of the arterial wall, if confirmed, would constitute additional evidence for this hypothesis.

Another unexpected finding has focused our attention on these possibilities. In about 2% of infants (less than 3 years of age), with aortas that were entirely negative for fatty streaks after gross Sudan staining, fine sudanophilic droplets in the cytoplasm of isolated cells or scattered small groups of cells in the inner layers of the arterial wall have been seen on histological and histochemical study of frozen sections of "representative" areas.[13] Many of these cells occupy the position and have the appearance of smooth muscle cells. Thus, we have seen intracellular lipid without extracellular lipid but never the reverse, and this again emphasizes the role of the mesenchymal cells in the earliest stages of atherogenesis and supports the concept of local formation.

To us, the most impressive evidence for local formation is derived from studying hundreds of aortas, coronary arteries, and other arteries collected from various parts of the world; data from accidental deaths were obtained from medicolegal laboratories, and data from deaths due to natural causes were obtained from routine autopsy services in large general hospitals in metropolitan areas (New Orleans; Guatemala City; San Jose, Costa Rica; San Juan, Puerto Rico; Cali, Colombia; Bogota, Colombia; London; Madrid; Barcelona, Spain; and Durban, Union of South Africa). Practically everyone beyond the age of 3 years has shown some degree of fatty streaking of the aorta, and this has been confirmed by gross Sudan staining and microscopic study. The similiarity in the pattern of development of fatty streaks in regard to age in various parts of the world has been striking.[14] Individual differences in each of the areas are marked, but the composite picture for each area is similar to that of other areas—despite the marked variations in genetic background, diet, climate, habits, indigenous diseases, and other factors. It is difficult to believe that each of these persons has consumed too many calories, too much fat, too little protein, too much or too little animal fat, or too much or too little unsaturated fat or that each has had hypertension or some other disturbance that could have left scattered "scars" in the arterial wall that predisposed to differential filtration. It is easier to believe that the arterial wall normally forms and turns over to the metabolic pool lipids not unlike those in the circulating blood and that local imbalances in this normal mechanism result in the local accumulation of lipid that constitutes the first stage of atherosclerosis.

Evidence against local formation is indirect and consists largely of the fact that mesenchymal cells (smooth muscle cells, fibroblasts, and phagocytes) in other parts of the body do not form and accumulate lipids except under special conditions, as exemplified by xanthelasma and xanthoma tuberosum. It must be remembered, however, that the arterial wall is the only pulsatile organ in the body, and this turbulent environment—created by a primary pulse from the lumen and a counter pulse from the vasa vasorum—must afford opportunities for physicochemical activity that are lacking or limited in other parts of the body.

In summary, the logic for filtration and against local formation is far outweighed by the increasing number of direct observations supporting local formation and opposing filtration. The arterial wall is an organ in its own right and should be recognized as such.

Comment

Let us turn now to some of the implications and possible applications of this newer approach to the pathogenesis of atherosclerosis. Two forces are at play: lipid accumulation and reaction to these lipids. This reaction may be (1) superficial, as by incrustation of fibrin (Rokitansky and Duguid), or (2) deep (fibrosis, necrosis, hyalinization, and calcification). The first of these forces is the first stage of atherosclerosis (fatty streaking), and the second constitutes the second stage of atherosclerosis (fibrous plaques).

A third force may come into play, namely, complication of lesions, which constitutes the third stage of atherosclerosis. This may be of local or of systemic origin. Among the local factors that are recognized, these can be listed: hemorrhage due to local vasoconstriction about the margin of one or more fibrous plaques, softening of one or more plaques with ulceration and thrombosis, and embolism (rare). At least two systemic factors are recognized: accretion of additional lipid (related to stage 1) on the surface or about the margins of one or more fibrous plaques and variations in the coagulability of the blood. Whether clinical disease, the fourth stage of atherosclerosis, becomes manifest will depend on the size of the vessel involved, the rate and degree of occlusion of its lumen, and the potential for collateral circulation about the point or points of constriction.

Thus, in order to understand the natural history of this protean disease, it is essential to recognize that different factors may be responsible for the different stages of atherosclerosis. Much confusion has arisen from translation of data among various species of animals and failure to keep proper perspective on the various stages of atherosclerosis. For example, reference is frequently made to the fatty streaks in the aorta and coronary arteries of cholesterol-fed rabbits or chickens with the inference that these data might be pertinent to clinical coronary artery disease in man. Not only does this type of reasoning ignore interspecies caution but it refers the first stage of atherogenesis in one species to the fourth stage of atherosclerosis in another species. Even if the enzyme systems and other mechanisms for lipid transport in the two species were the same—and there is ample evidence that they are not—there still remains the probability that lipid transport has little or no effect on the final episode (complication of one or more strategically located fibrous plaques by hemorrhage or thrombosis) that precipitates the clinical coronary artery disease. We do not wish to belabor this point too much, for there is the possibility (albeit an improbability) that accretion of additional lipid on the surface of a fibrous plaque could be the mechanism of final narrowing to the point of clinical coronary artery disease. Thus, it is conceivable that persistence in the use of these factors which discourage lipid accumulation in the arterial wall could favorably affect the fate of some of the fibrous plaques in the coronary, cerebral, and other arteries. But it is not fair to expect this mechanism to prevent the common complications (hemorrhage and thrombosis) that precipitate clinical disease.

Much of this confusion can be avoided by observing interspecies caution and recognizing the probable stage of the disease in man at any given age. In general, it can be stated that the first two decades of life are concerned with the first stage (fatty streaking), the second two decades with the second stage (conversion of some of these fatty streaks to fibrous plaques), and the third two decades with the third stage (complication of lesions) of atherosclerosis (fig. 2).

But to return to the major thesis, how does lipid accumulate in the arterial wall? There is a growing body of evidence indicating that active metabolic work is performed by the mesenchymal cells in the inner layers of the arterial wall, that the arterial wall is indeed an organ, and that it is a potential target organ for hormones or hormonal imbalance.

Enzymes in the mesenchymal cells in the inner layers of the arterial wall must come into play before visible fat makes its appearance. It is probable that similar enzymes effect the transport of lipid moieties across the endothelial barriers, but it is strange that visible lipid has not been observed in the cytoplasm of endothelial cells. There is ample evidence that the simplest of building stones, labeled acetate and phosphate, can be utilized for fabrication into cholesterol, phospholipid, and other lipids by the perfused, sliced, or in situ aorta. There is no question about the ready diffusibility of these ions, but it is by no means certain that the major portion of lipid transport across the arterial wall occurs in this form. Thus, the problem is basically one of the relative importance of the transport of lipoproteins versus the transport of more simple molecules. And it is probable, from the natural history of the process of lipid accumulation and the ready dissociation between lipid concentration in the blood and lipid accumulation of the arterial wall, that lipoproteins must be enzymatically dissociated before passing the endothelial barrier and bathing the mesenchymal cells in the inner layer of the arterial wall.

STAGE 1	STAGE 2.	STAGE 3.	STAGE 4
Fatty Streak →	Fibrous Plaque →	Complications of Lesions →	Clinical Disease
0-19 years	20-39 years	40-59 years	over 40 years
Due to local accumulation of lipid (under enzyme-hormonal control ?)	Reaction to concentration of certain lipids (and incrustation of fibrin ?)	Hemorrhage Thrombosis Accretion Embolism Calcification	Myocardial infarction Stroke Gangrene

Fig. 2.—Concept of pathogenesis of atherosclerosis.

In summary, then, it would seem that the emphasis should be shifted to active metabolic work and that efforts should be directed toward the detection, concentration, and possible clinical utilization of active principles that govern lipid transport and local accumulation. The best available evidence points to these active principles being enzyme-hormone complexes.

Summary

Enzyme-hormonal principles that govern lipid transport at the cellular level appear to play a greater role in lipid accumulation in the arterial wall (stage 1 of atherosclerosis or fatty streaking) than do physicochemical factors governing filtration through the arterial wall. Other factors come into play in the subsequent development of these early lesions through stage 2 (fibrous plaques) and stage 3 (complication of lesions, as by hemorrhage and thrombosis) to stage 4 (clinical disease). Much confusion regarding human atherosclerosis can be

avoided by observation of interspecies caution and recognition of the probable stage of the lesions in man at any given age.

PATIENTS WITH MULTIPLE INJURIES.—There were 9,500,000 accidental injuries in this country in 1957, with 95,000 deaths. . . . With increasing frequency we are confronted with persons injured in two or more sites and possibly affected in two or more body systems. The immediate problem is then saving life, to be followed after first aid by determination of the order of care of the various injuries in such a way that first things are done first. This can be accomplished only by organization. . . . The important factor in this organization is the team captain. In a large hospital this should be preferably a general surgeon, not a specialist. In a smaller community hospital it might well be a general practitioner. The function of the team captain is to take complete charge of this multiple injury patient. He should call on whatever specialists are required, but the treatment which they recommend should not be instituted until the captain orders it at a time when he believes that the patient can stand it. . . . It is the team captain's duty to remain with this patient constantly for as many hours as are required, giving all the orders, seeing all the x-rays and laboratory reports, discussing viewpoints with the specialists, changing the order of procedures as changing conditions require. This one man must accept the responsibility for the life of this patient. It is no place for two attending physicians or an attending physician and a resident to be both ordering, possibly at cross purposes. . . . Trauma and the first principles of its management . . . is not a specialty and it should not be, since it cuts across all parts of the human body. . . . With the extensively injured, no rules can be laid down to cover all cases, but there are certain principles to guide us, thereby not adding surgical trauma until it can be tolerated and not delaying reparative surgery until the progress of infection becomes more than the body can cope with.—R. H. Kennedy, M.D., The Appraisal and Management of Patients with Multiple Injuries, *The Surgical Clinics of North America,* December, 1958.

THE CLINICAL RADIOLOGIST AND THE PROBLEMS OF RADIATION HAZARDS

Wendell G. Scott, M.D., St. Louis

Mankind must learn to live safely in the artificial environment that is being created by the atomic industrial revolution. That this can be done is illustrated by the fact that 38 million radiologic examinations are done annually in the United States alone; diagnostic radiology is indispensable, and if it contributes to the shortening of life span and production of genetic damage such effects have not made themselves evident. The problem is first to understand and second to minimize the effects that can arise from diagnostic radiologic examinations. During the first 30 years of life the gonadal dose should be strictly limited according to published recommendations; in the later years of life, beyond the reproductive period, the gonadal (genetic) effects are of no clinical significance. However, exposure to ionizing radiation should be minimized by methods outlined here. People should not be frightened by confusing diagnostic radiology with thermonuclear warfare and should learn that the safe use and control of medical radiation depends on properly educating its users in the underlying sciences.

This is the nuclear age. From the time man first utilized fire, he has struggled to develop and then to master each new and more powerful source of energy. Significantly, he has also learned to protect himself from the hazards generated by them. Man is certain to do the same with the power and radiations arising within the atom.

We have been living in the formative period of the nuclear era for 16 years. The problem today is one of control of radiations so that man can live safely in the artificial environment which the atomic industrial revolution is creating. In essence, we must prepare now to safeguard a brilliant future by keeping all forms of ionizing radiation at the lowest possible level.

Public Health Aspects

The public health aspects created by the nuclear age are the responsibility of the medical and allied professions. The leadership in the medical use of radiations has logically devolved on the radiologists, the radiation physicists, the radiobiologists, the health physicists, and the geneticists. Their representatives constitute the National Committee on Radiation Protection as well as the International Commissions on Radiation Protection and on Radiological Units and Measurements. Since 1931, these bodies have formulated the standards for the safeguarding of patients, occupational personnel, and the public. Their recommendations have proved to be fully protective, practical in application, and effective without legislation—a remarkable record.

The work of these bodies provided the foundations for the handbooks on radiation of the National Bureau of Standards. These contained most of the recommendations emphasized in the 1956 reports of the National Academy of Sciences on "The Biological Effects of Atomic Radiation" [1] and of the British Medical Research Council on 'The Hazards to Man of Nuclear and Allied Radiations." [2] These reports served to focus the attention of the public on this subject, to publicize the genetic hazard that can accrue from small amounts of radiation, and to intensify the efforts of the medical profession to minimize radiation dosage from the use of x-rays.

Volume of Diagnostic Radiologic Examination.—Diagnostic radiology has had a tremendous growth because of the great contributions it has brought to the health and well-being of mankind. This was not due to accidental circumstances. It came about because it was and still is the means for lifting the cloak of uncertainty from medicine. Nearly every practicing physician either directly or indirectly utilizes the indispensable advantages offered by diagnostic radiology for the benefit of his patients. The total number of radiologic examinations and the films consumed per year are in the millions. Estimated annual numbers are as follows [1b]: 38 million roentgenographic examinations, with 32 million by radiologists; 118 million sheets of film; 13 million fluoroscopic examinations, with less than half by radiologists; 3 million photofluoroscopic examinations in hospitals; 189 million packets of dental films; 15 million to 18 million square feet of industrial film; and 128,000 roentgen ray machines, with 50% owned by dentists and 50% by physicians, osteopaths, chiropractors, and chiropodists (about 50% of general practitioners own diagnostic x-ray equipment, and the number of physicians owning equipment increased 50% from 1949 to 1955).

Professor of Clinical Radiology, Washington University School of Medicine.

Chairman's address, read before the Section on Radiology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

To keep these figures in the proper perspective, let us not forget that the great bulk is made on sick people, on those seriously ill with an obviously short life expectancy, and on those over 30 years of age. Nor should we overlook that during the past 50 years, simultaneously with the expansion of diagnostic radiology, the life expectancy increased from 49.2 to 68.07 years; the death rate from tuberculosis dropped from 194 to 9.1 per 100,000; infant mortality fell from 99.9 to 26.4 per 1,000 live births; and fetal deaths dropped from 23.9 to 17.1 per 1,000 live births. Also, American children today are said to be taller and healthier and have a lower death rate than before. Stone,[3] who assembled these statistics, points out that while radiology cannot lay claim to being the major reason for these great medical achievements it played a conspicuous part. His inference is that if radiations of this order contribute to the shortening of the life span and produce genetic damage they have not made themselves evident.

Deleterious Effects of Radiation.—In the assessment of the possible deleterious effects arising from the medical and dental use of x-rays, it must be clearly understood that (1) only small doses of radiation are used in clinical examinations and (2) the exposures are limited to local or segmental areas of the body as opposed to total-body irradiation. Many of those who emphasize the bad effects of diagnostic exposures do not distinguish between local and total-body radiation. The "roentgen" is the measure of exposure to each gram of tissue, and 1 r to a toe is vastly different than 1 r of total-body exposure.[3]

The deleterious effects of radiation of this order fall into two broad categories: (1) the somatic effects, which depend on the exposure to the body tissues and are primarily of immediate concern to the individual person, and (2) the genetic effects, which depend on the exposure to the gonadal tissues and are of long-range concern to the human race.

Somatic Effects of Radiation

Shortening of Life Span.—A somatic effect which has created consternation is the life-shortening in animals which have received whole-body irradiation. However, it has not yet been shown to result from low doses of the order of background radiation or from those used in diagnostic examinations, nor has it been shown to occur from segmental or partial-body irradiation. It has been described as an acceleration of the aging process rather than as a consequence of a specific radiation lesion. This complication apparently has a direct dose-size relationship, but such data are not available for man.

In 1956, Whipple[4] warned that a person who received the maximum permissible exposure of 0.3 r per week would accumulate a total dose of 468 r in 30 years, which might reduce the life expectancy of the exposed person about three years. Russell's[5] data from mice suggest that a continuous exposure at the rate of 15 r per year might result in a 3 to 5% shortening of the life span. Jones[6] estimated the life-shortening in man from exposure to radiation as 15 days per roentgen—a figure much higher than that of others. More recently, Failla[7] estimated a shortening of approximately one day per roentgen of accumulated dose from chronic exposure at a dose rate not in excess of 0.5 r per day, which amounts to three-fourths of a year.

Warren[8] concluded that radiologists die on the average of 5.2 years earlier than do other physicians. After a careful appraisal of Warren's data, Seltser and Sartwell[9] stated: "That the average age of radiologists at death is younger than that of other physicians cannot be ascribed to their exposure of ionizing radiation, since differences in age composition alone can account for the finding." A recent survey by Brown and Doll on 1,377 British radiologists confirms this opinion, for they conclude: "The expectation of life of British radiologists is similar to that of other men of comparable status and has not been substantially altered by their occupational exposure to radiation." From studies on radiation exposure to radiologists, Braestrup[10] concludes, "If reduction in life-span is proportional to the dose received, it may be inferred that radiologists using present safeguards, do not need to fear any significant future reduction in their life-span due to irradiation."

Leukemia.—Another somatic effect of concern is the possibility of inducing leukemia. For a reason as yet unknown, it has shown a real increase in incidence in the past 20 years. The suspicion that the expansion of diagnostic radiology may be related to this increase arose from the following observations:

Leukemia can be induced in animals as a result of large doses of whole-body exposure to radiation. Deaths from leukemia among U. S. radiologists are reported to be 10 times that of other groups of physicians, based on 8 cases in 173 radiologists over a 15-year period (1929-1943).[11] In England between 1935 and 1954, a total of 13,352 patients were given radiation treatment with large doses for ankylosing spondylitis and 38 cases of leukemia appeared.[12] In 1,400 infants and children who received deep x-ray therapy for "thymic enlargement" over a 25-year period, 7 cases of leukemia were found (1926-1951).[13] The incidence of leukemia in the 98,000 survivors of the atomic blasts near the hypocenter at Hiroshima City was 12 times greater than those at the periphery. The total number of known cases of leukemia among the 194,000 exposed survivors at Hiroshima and Nagasaki up to 1955 is 93.[2] No cases of leukemia have been reported during the first decade in Japanese children who were irradiated in utero by the atomic bomb. Stewart and associates[14] reported that children of mothers who received radiation exposure to the abdomen from diagnostic procedures while pregnant developed leukemia nearly twice as frequently as the controls—42 as compared to 24. In this situation, the fetus received total-body irradiation. However, in those mothers who had diagnostic x-ray examinations of other portions of the body there was no increase in the number of children developing leukemia.

This is a total of 188 people developing leukemia after total-body or near total-body irradiation, 93 of whom were irradiated by atomic bombs. This is a small number on which to base sweeping conclusions and is inadequate to establish the linearity effect of radiation in leukemia. Lewis,[15] however, ably presents the argument in favor of this concept.

Of equal importance in assessing the leukemogenic effect of radiation is the series of 640 women treated by Kaplan [16] for infertility by irradiating the ovaries; in neither they nor their offspring for two generations have leukemia, lymphoma, or cancer developed. Likewise, no cases of leukemia have appeared in Arneson's series of 350 women with primary carcinoma of the cervix who have been studied 5 to 20 years; all received heavy external x-ray radiation and local radium treatments.

Brues, discussing the somatic mutation theory as the cause of leukemia, states: "There must be something besides one mutation in one cell. Maybe it might be in two or three mutations in the same or adjacent cells in which case it would not be a linear relation. It might possibly be a combination of things with which radiation has nothing to do. We just don't know."

In summary, it is evident that total-body irradiation by either large single or cumulated doses causes an increased risk of developing leukemia, and unnecessary exposure to ionizing radiation should be avoided. We have no precise knowledge of the incidence of leukemia under conditions of chronic exposure. The somatic effects from radiation present an ever-constant threat to occupational personnel but pose only a remote threat to the patient undergoing a diagnostic examination; those who have followed the recommended precautions and the directives on protective barriers have not sacrificed any appreciable period of their life span or incurred a serious risk of developing leukemia.

Genetic Effects of Radiation

The problem, then, is first to understand and second to minimize the genetic effects that can arise from diagnostic radiologic examinations. The inheritance mechanism is by far the most sensitive to radiation of any biological system in the human body. To quote from Glass [17]:

> One must begin to think of mutations of the hereditary material in terms of its chemical nature. . . . Chromosomes, the carriers of the genes, are composed of deoxyribose nucleic acid (DNA), some ribose nucleic acid (RNA), a considerable basic protein (histone), and a little protein of a higher molecular weight. The evidence indicates that the genetic information is coded primarily in the DNA. . . . Mutations are alterations in this material which, when chromosomes reproduce themselves, are themselves replicated and thus transmitted through mitotic cell divisions.
>
> The hereditary material is of course present in the nuclei of all cells, not of reproductive cells alone. Any damage done to it is transmitted through mitoses to all the somatic descendant cells. Many, if not all, genes are concerned with presence and specificity of particular enzymes, each of which governs some particular step in the metabolic pattern. When a mutation impairs the specificity of an enzyme and thereby blocks a particular metabolic step, the usual outcome is fatal unless the cell has some alternative way of supplying its needs. . . . This is not serious if there are uninjured cells to take its place. Only if the damaged cell is irreplaceable, or stimulated to abnormal activity and multiplication at the expense of other cells, such as in leukemia or cancer, is the fate of the entire organism imperiled. If great numbers of somatic cells are damaged genetically, the effect may be severe, even though not uniform in character. Thus, most mutations do not result in conspicuous abnormalities, but are manifested as increases in the types of abnormalities, disease, and death that are already occurring.

Furthermore, radiation acts blindly, not selectively, on certain genes and not on others, which explains why the vast majority of mutations are deleterious. In genetic damage to the reproductive cells, the hereditary defect will be present in every cell of the offspring to whom it is transmitted via egg or sperm and no tissue can escape the consequences of the defect. The sole safeguard in each of such cases is the general probability that the *set of genes inherited from the other parent* will not carry the same defective genes.

It is not possible to make a simple, noncontroversial statement concerning the implications for man of the genetic effects of radiation. There is, however, general agreement among geneticists on the following basic concepts which have been extrapolated from data on the fruit fly and mice: 1. Apparently no threshold dose is required to produce a deleterious effect. 2. Once damage is done, it is largely irreversible. 3. The effects are probably cumulative over the years. 4. The result of genetic damage is to produce deviations from the norm in the offspring of the irradiated parents. 5. These deviations or mutations are almost always *undesirable. Their offspring are called mutants.* 6. Mutations produced by radiation are in no way different from mutations which have always been occurring in the human race. 7. The mutants are characterized in general as follows: decreased longevity, increased susceptibility to disease, decreased fertility, and usually recessive or masked so that the first-generation offspring do not bear the full brunt of the genetic damage. Thus, contrary to public opinion, freaks and monstrosities do not often occur in the first generation after a mother is irradiated. Usually the deviations caused by the damaged gene in the first offspring are so minute and subtle that recognition is extremely difficult. The full expression of the damage comes in subsequent generations when there is a mating of those with similarly damaged genes.

There is a certain level in the mutation rate which is known to be normal for the human species. The concern of the geneticists is that this level may be significantly raised from the widespread and increasing use of ionizing radiation. It has been estimated from Drosophila flies and mice experiments that a gonadal dose of 30 to 60 r to each person in the entire population would result in a doubling of the normal mutation rate. The geneticists fear that such a possibility would be disastrous for the perpetuation of the race. Remember that the geneticists are interested in total population doses, i. e., "x" millions of roentgens per "y" millions of persons in the reproductive age. Persons beyond the reproductive age can have roentgenographic examinations without fear of genetic damage.

TABLE 1.—*Seven Types of Examinations Yielding Surface Dosage in Excess of One Roentgen over Gonads**

Examination	r†
Angiocardiography	1.5
Excretory pyelography	2.25
Pelvimetry	4.9
Lumbosacral spine	5.4
Upper gastrointestinal (fluoroscopy plus roentgenography)	5.7
Routine spine	5.8
Hip and pelvis	8.8

* Data from Hodges.[18]

† Doses are given as surface values, and, obviously, gonadal doses are measurably less, especially in the female.

The Committee on Genetic Effects of Atomic Radiation of the National Academy of Sciences [1a] recommends that during the first 30 years of life the average gonadal dose for large populations should not exceed 10 r of man-made radiation plus the 4.3 r from the natural background sources. Persons should not receive a total cumulative dose to the reproductive cells of more than 50 r up to the age of 30 and not more than another 50 r, or a total of 100, to the age of 40.

It would be of great help in determining the extent of the genetic problem if we knew the average gonadal dose the population was now receiving from medical and dental sources and how it compares to natural background radiation. Laughlin and Pullman [1b] attempted to do this by a survey of the literature and estimated it to be 4.6 r ± 3 in a preliminary report that has not been officially released by the National Academy of Sciences. This figure is based on data of varying reliability. The report in October, 1957, by the International Commission on Radiological Protection and International Commission on Radiological Units and Measurements states, "Enquiries up to the present have not revealed any records detailed enough to use for the proper assessment of the gonadal doses to the population," and concludes, "Consideration of methods of arriving at the genetically significant annual gonad dose, to the population from medical exposures is the most important immediate objective." In a subsequent paper, Laughlin and associates discuss the studies and surveys that are required for obtaining the necessary information to develop this figure. The United Nations Scientific Committee on the Effects of Atomic Radiation requests the cooperation of the medical profession in supplying records for this purpose. Until this is done and an accurate estimate of the genetically significant gonad dose determined, we must be extremely cautious about accepting or formulating quantitative inferences from diagnostic x-ray procedures. Sonnenblick reminds us that those "which have appeared in scientific literature and publicized in mass media can only be regarded as 'best guesses' and conclusions drawn cannot be considered as definitive." In other words, one must be most careful in the interpretation of studies on uncontrolled data.

To summarize, the science of genetics has become of clinical importance. Ionizing radiation in small doses unquestionably can increase the mutation rate in the hereditary material and any increase in the mutation rate is undesirable for the human race. No matter what the present average gonadal dose is, it is too high if it can be lowered.

Means of Reducing Gonadal Exposure

These conclusions are not a pronouncement of doom for radiology. They are a challenge and a stimulus to do a better and a more careful job. Just as there are advances in other fields of medicine from the development of new knowledge and ideas, so there are in genetics and radiology. New roentgenographic techniques and procedures have to be developed, old ones modified, and others discarded. With use of present-day developments radiation dosage from the medical use of x-rays can be reduced by 75 to 85%.

It can be accomplished while preserving the value and without impairing the efficiency of the diagnostic examination. To bring this about, it is necessary that physicians have a sound understanding of the hazards as well as a knowledge of how to use diagnostic radiology and how to employ protective measures. To aid in this undertaking, the American College of Radiology (aided by a grant from the Rockefeller Foundation) has distributed to all practicing physicians "A Practical Manual on the Medical and Dental Use of X-rays

TABLE 2.—*Frequency of Utilization of Examination Carrying High Gonadal Dosage, 1956-1957**

Examination	Times Used	Patients Aged Under 30 Yr. No.	Patients Aged Under 30 Yr. %
Upper gastrointestinal	4,804	602	12.5
Routine spine	1,132	260	23.0
Lumbosacral spine	2,122	544	25.5
Excretory pyelography	1,795	525	29.0
Hip and pelvis	2,538	909	35.5
Pelvimetry	370	260	70.0
Angiocardiography	147	115	78.0

* Data from Hodges.[18]

with Control of Radiation Hazards" (copies of this manual may be obtained by writing directly to the American College of Radiology, 20 N. Wacker Dr., Chicago). It is well for physicians who do fluoroscopic and roentgenographic examinations to realize that they have a greatly increased liability because of the possibility of inducing genetic damage by radiation.

The physician who first examines the patient assumes the responsibility for determining if the possible benefits of the examination outweigh the possible hazards. If in doubt, he should consult his radiologist. This is a just responsibility of the attending physician and one which must not be compromised or restricted by the enactment of legislative controls. Above all, we must not forget that our primary concern is with the welfare of the patient. The health of future generations is based on the health of the present generation.

Fortunately, about 85% of the total diagnostic (gonadal) dose arises from six or seven types of examinations, which constitute only about 10% of all examinations. Hodges[18] found that only seven standard procedures exposed the gonads to radiation in excess of 1 r per examination and that these constituted only 20% of his annual total of 64,076 examinations. Table 1 is a list of these procedures arranged in order of magnitude of gonadal dose.

In table 2 is listed the frequency of the seven examinations carrying high gonadal dose arranged in the order of increasing numbers of those that are given to patients below the age of 30. These total 3,215 cases, or only 5% of the total of 64,076 examinations, indicating that only a small percentage of roentgenographic examinations are performed on persons under 30 years of age. They are only a few patients in any one working day, and so their protection with gonadal shields does not constitute a burden for the staff.

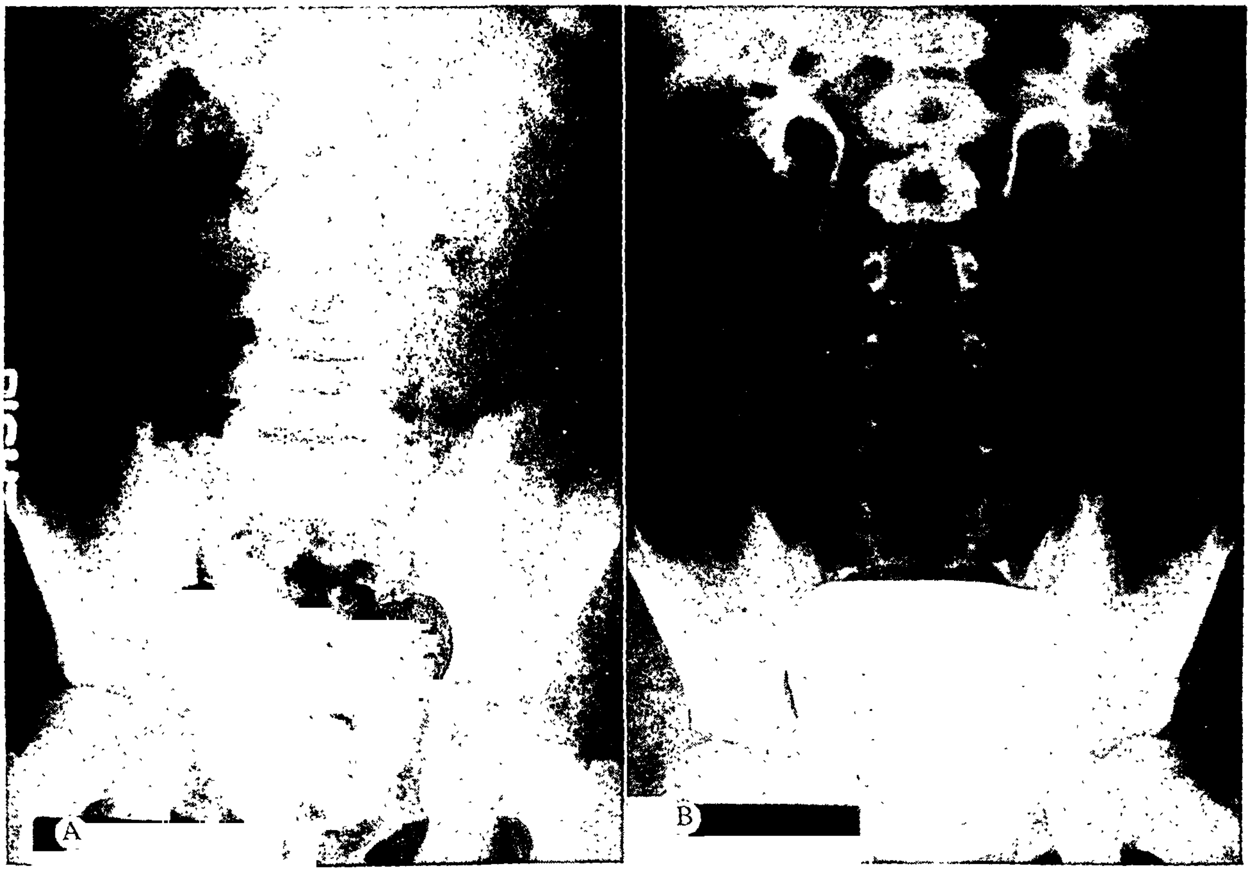

Fig. 1.—*A*, preliminary roentgenogram of urinary tract of 12-year-old girl prior to intravenous pyelography (made without gonadal shield for detection of possible urinary calculi). *B*, subsequent pyelograms made with lead shield cut out to cover pelvic inlet to reduce radiation exposure to ovaries.

The adoption of three fundamental practices can result in an appreciable reduction in the gonadal dose: 1. Diagnostic examinations should be performed by physicians with training in radiology and by experienced x-ray technicians. The examinations must be of standards acceptable to other physicians to whom the patient may be referred to avoid having the examination repeated. 2. Written reports and films of each examination must be preserved so that they may accompany the patient if he is referred to another physician, hospitalized, or transferred to another city. 3. The initial examination should be made carefully. The patient should be properly posed, and he should be kept under control to avoid unsatisfactory films and the necessity of retaking them.

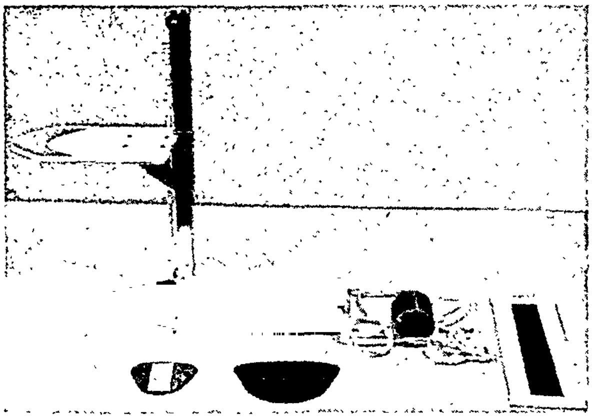

Fig. 2.—Collection of various devices for shielding gonads: testicular shield on adjustable stand (Hodges); molded lead cup for shielding testes (may be tied in place to permit placing patient in various positions); lead sheet cut out to conform to pelvic inlet for ovarian shield; heavy lead-rubber sheeting (used for same purpose); and rectangular lead-rubber sheets, used in many examinations as gonadal shields in either males or females.

A guiding directive for lowering gonadal dose might be as follows: Scrutinize every examination for ways of minimizing gonadal dosage. With this objective in mind, let us see what can be done at the present time.

First, consider the appropriateness of the examination and equipment: (*a*) have a solid reason for the examination—it is doubtful if many unnecessary examinations are being done because the need is being more carefully evaluated and the expense serves as a deterrent; (*b*) take only the films that are required to elucidate the examination—eliminate nonessential views; (*c*) discourage health-insurance policies that include "free" x-ray examinations, and encourage policies of the deductible type so that the patient must pay for a portion of the initial examination; (*d*) limit fluoroscopy to specific purposes, especially in children, for it yields the highest gonadal dose, the gonads are more difficult to shield, and it can result in whole-body irradiation to infants—keep in mind that one minute of continuous fluoroscopy can be equivalent in radiation to 400 chest films; (*e*) have a radiation physicist survey your roentgenographic and fluoroscopic equipment for possible "leaks," obsolescence, output in roentgens, adequacy of protective barriers, and provisions for protection of occupational personnel; and (*f*) teach x-ray technicians the importance of lowering gonadal exposure—they must know the "why" for each factor employed because the largest exposure reduction results from the correct technique the first time without having to make corrections and repeat the examinations.

Second, reduce the quantity and improve the quality of the x-ray beam (reduce entrance skin and integral dose) by the following means: (*a*) addition of 2 mm. of aluminum filtration to roentgenographic tubes and 3 mm. of aluminum filtration to fluoroscopic tubes (gain in dose reduction 50%+); (*b*) increase target-film distance to 36 or 40 in. for roentgenographic work and target-table distance for fluoroscopy to 18 in.—the increased distance produces less exposure to the patient in relation to the amount reaching the film or screen (gain in dose reduction 10%+); and (*c*) collimate diagnostic beam to the smallest area that covers the part to be examined—adjustable multileaf diaphragms with rectangular apertures can reduce stray radiation as much as 20 to 30% over circular cones—and, in this connection, we must continue our efforts to develop techniques that will provide objective evidence on the roentgenogram that the exposure was confined to the area under investigation (gain in dose reduction 15-30%).

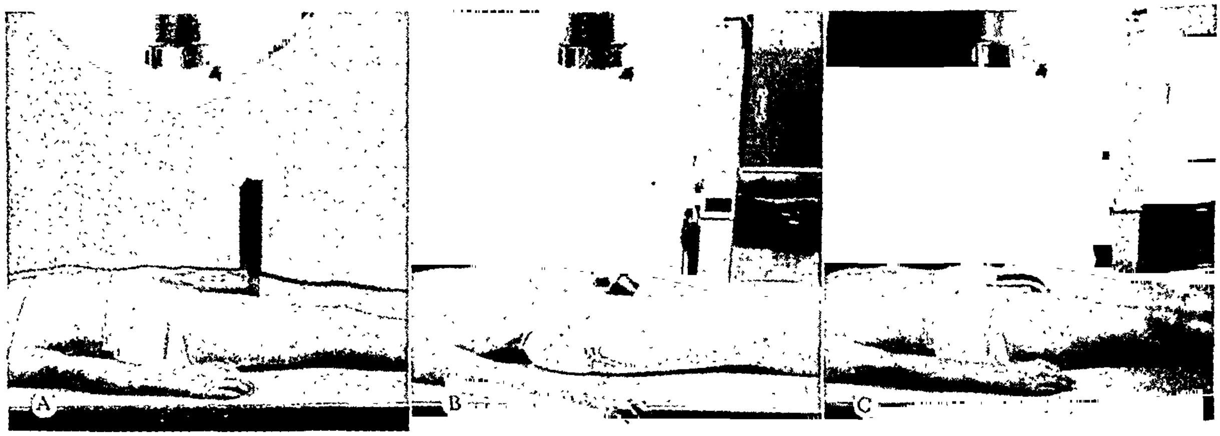

Fig. 3.—Three different methods of using testicular shields: *A*, Hodges' stand; *B*, molded lead cup; and *C*, lead-rubber sheeting.

Third, increase effectiveness of film dose by the following means: (*a*) use the new film with fast emulsion (gain in dose reduction 40-50%); (*b*) use high-speed intensifying screens (gain in dose reduction 40-50%)—fast films plus high-speed screens alone can yield a 75% reduction; and (*c*) process films with time and temperature control with use of the recommended chemicals for fast film (Spenodone hydroquinone developer reduces film dose 20%) (gain in dose reduction 5-20%).

Fourth, investigate use of special equipment: (*a*) phototiming, which is of decided help in preventing overexposure and underexposure and, therefore, in decreasing the number of reexaminations, and (*b*) fluoroscopic image intensifiers, advantageous in reducing exposure to both patient and operator in prolonged fluoroscopic studies, such as in cardiac catheterization and myelography.

Fifth, utilize gonadal shielding devices (fig. 1): (*a*) lead, lead-rubber, or lead–glass-fiber sheets or aprons or lead barriers to cover the pelvis for most radiographic procedures (fig. 2) and (*b*) special devices as shown in figures 3 and 4—adjustable tripod stand (Hodges), molded lead cups for males, lead or lead-rubber cutouts conforming to pelvic inlet for females (fig. 1), and lead-rubber snap-on diapers for infants (considerable gain in dose reduction).

Sixth, note special protective measures for pregnant women (30% of all gonadal dose comes from obstetric radiography): (*a*) reduce to a minimum roentgen exposures to the pelvic area of women in child-bearing age in the two weeks after the last menstrual period to preclude the possibility of irradiating the embryo and (*b*) when possible, delay abdominal and pelvic exposures on pregnant women until the last trimester.

Comment

The careful exercise of these practices not only will materially lower radiation dosage to the germinal tissues but will avoid a severe restriction of survey examinations in public health and permit the inclusion of new radiologic procedures that will be developed in the future. The purpose of this study is to show how the dosage can be lowered for almost all examinations. It is not a plea to reduce the number of radiologic examinations below that required for the highest quality of medical practice but to support their utilization through a lowering of the gonadal dosage.

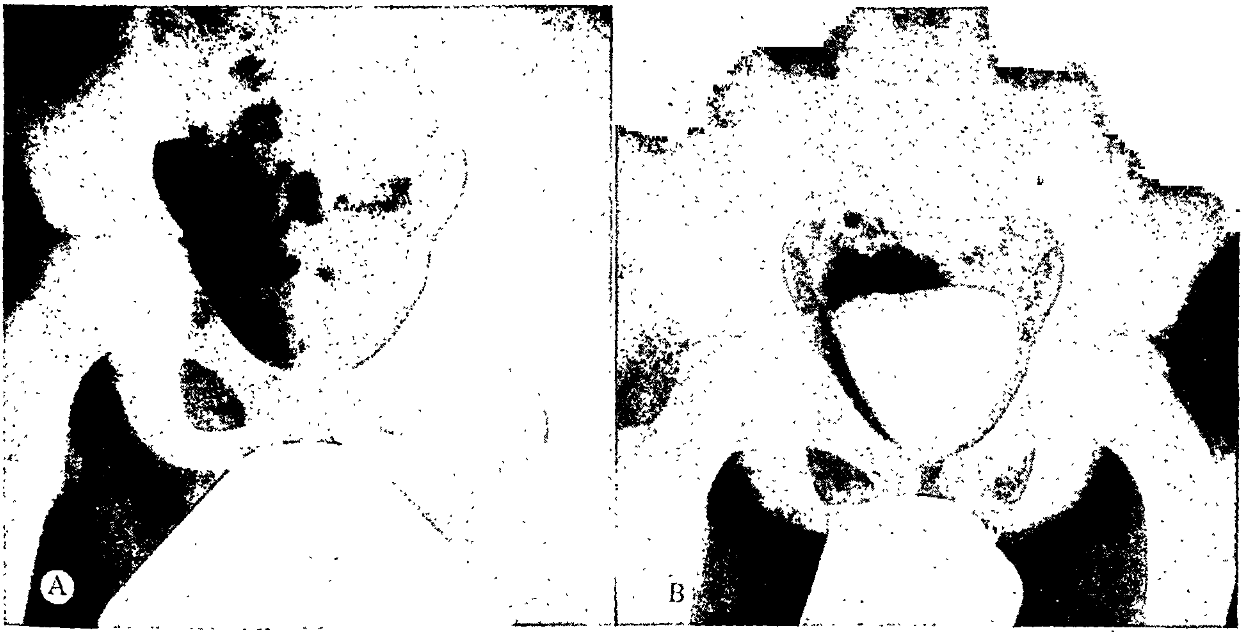

Fig. 4.—*A*, roentgenogram made with Hodges' testicular shield in place. It does not obscure bones of pelvis or hinder examinations of hips and femurs. *B*, roentgenogram made with molded lead cup in place, obscuring only small area of inferior pubic rami, yet affording complete visualization of hip joints and bladder for cystograms, as in this case, and not obscuring information in intravenous pyelograms.

Conclusions

The time has arrived to (1) develop a calm and mature attitude toward the nuclear era, an era that holds great promise for the betterment of mankind; (2) put an end to the psychological scare about medical radiation and stop confusing it with thermonuclear warfare, with acute massive or chronic whole-body irradiation, and with the restrictions for those occupationally exposed; (3) have every physician using diagnostic radiology exert positive efforts and means to keep radiation dosage to the gonads to the lowest level consistent with the best standards of medical practice (as radiologists, we must set the example); (4) acknowledge that radiation to the germinal tissues can be reduced by 75 to 85% without impairing the efficiency of diagnostic examinations; and (5) realize that the key to implementing the safe use and control of medical radiation lies in the education of all practicing physicians in the fundamentals of genetics, radiobiology, and radiology.

RESEARCH AND TRAINING

Conrad A. Elvehjem, Ph.D., Madison, Wis.

Education is a human experience, and methods of training are many and varied. Medical education, perhaps better than any other field, illustrates the progress of teaching through the years—how new ideas and methods developed and how the best of them were carried forward and augmented by later ideas and methods.

History of Medical Education

Dr. William S. Middleton traced this history some years ago, when he was dean of the University of Wisconsin Medical School, from its origin in the priesthood of antiquity to the modern medical school. In the evolution of Greek culture, medicine was eventually separated from the priesthood. The first medical school at Alexandria, founded by Alexander of Macedonia, trained such notable medical figures as Herophilus, Erasistratus, and Galen. With the Roman conquest of Egypt, the school at Alexandria was disbanded, and it fell again to the church to bridge the gap until the establishment of the next formal medical school at Salerno in the ninth century.

The torch of medical education lighted at Salerno was kept bright for at least four centuries, but its decline Dr. Middleton put at the 13th century when the medical leadership passed in turn from Bologna to Naples to Montpellier to Paris. True academic tradition in pageantry and form dates from the University of Paris. In France, surgery was separated from medicine. Leyden, Edinburgh, and London gained ascendancy in medical education in the late 17th and 18th centuries. The first medical school in North America was estab-

President, University of Wisconsin.

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 9, 1959.

lished at the College of Philadelphia in 1765. Until then, an apprenticeship system of medical education had prevailed in the United States.

While formal medical education showed a mushroom growth in the 19th century, the pattern of medical apprenticeship persisted in varying degrees throughout this period and, in a changed and restricted form, does today. The opportunity to read in an established physician's office was a coveted method of introduction to the study of medicine almost to the end of the 19th century in this country.

The formula for the first organized courses of medicine in America, Dr. Middleton reported, differed in no wise from the European or the British pattern. Classroom lectures and demonstrations were the rule. Personal dissection by the medical student was the exception.

Yet, among the leaders in medical thinking, there had long been the feeling that laboratory work—research if you will—was a vital part of medical instruction. This I have on the authority of Dr. Walter J. Meek, who, I might add, was the best teacher I ever had in my years of study at the University of Wisconsin. I might explain that I have never had the privilege of taking a formal medical course. Perhaps that is why I have been asked to speak on medical education.

But, seriously, my experience in teaching in allied educational fields has given me a respect for the combination of research and teaching, which may not be universal in the medical field. However, Dr. Meek not only was convinced of the effectiveness of this combination but felt that he was not alone among teachers with this point of view when he spoke briefly about it some years ago. This is what he said:

> Historically, research is probably quite as old an activity as teaching. Hippocrates, whose original works are not even preserved, was a clinical investigator of no mean merit.
>
> Aristotle would rank with present-day research embryologists. Both were teachers and research workers. However, the two activities were almost entirely separated from each other.
>
> When the master was a teacher, he donned his cap and gown, sat on a high stool, and read a book to the students. When he became a research worker he retired, often in secret, to a room in his house fitted up as a laboratory and he was accompanied only by a helper who might or might not be a student. The laboratory did not become a part of the professor's official equipment until the Italian Universities flowered at the end of the 16th century. Even for centuries after that, teaching consisted not in performing experiments or presenting very many demonstrations, but in reading what some authority had written on the subject. It was in this way that the books of Galen for 1,300 years became the scientific bible. Theoretically and practically anyone who could read, could teach.

The lecture, just like the apprenticeship, is still, in somewhat modified form, a backbone of our teaching today. A junior at Marquette University School of Medicine recently reported that he had listened and had taken notes in more than 1,400 lectures during his first two years of formal medical education. I have never measured our own program in this fashion, but I trust that ours, and most others, rely just about as heavily on the lecture method of teaching.

And I do not say this in criticism, for the lecture is a very efficient teaching method, but it is an immeasurably stronger method when coupled with experience. This is true for both teacher and student. Without experience, there is no way a lecturer can exercise scientific comparison or judgment, except on hearsay evidence.

Teaching can best stimulate the mind of the student when the mind of the professor is alive and questioning, as someone has put it, "when he is continually seeking new knowledge that will justify or correct his earlier impressions, when he kindles in the mind of the student by his own fire that lamp of truth which reveals all knowledge as an age-long and immortally unending search."

My first point, then, is that teaching must be a continual process of education for the teacher and that it can be carried out satisfactorily only when he constantly tries to enlarge his knowledge and test his ideas by an experimental method, which is research. I think that most of us can agree on that point.

The Student's Motives in Research

It is the second point in this regard on which we may have some differences of opinion. This is the value of student research in the teaching process. This point might best be put in the question: "How far should we go in encouraging a medical student to do research during his training career, and how can research activities be integrated with other teaching methods?"

Everyone in education does or certainly should recognize that the process of learning depends on how the student feels about what he is learning. If his feeling is negative, the learning will be negligible. If he wants to learn, learning can be much more rapid. Thus, the factor of motivation becomes a very important one.

In the field of medicine, many students are highly motivated often from a very early age, and this motivation is strengthened throughout training. However, I think it is important to keep in mind that every student has his own set of motivations, in medicine as in every other endeavor. Some may see in medicine a highly lucrative career and yearn only for the diploma as a certificate of a gilt-edged credit rating. These are not likely to be really educated by any method, and, for the sake of the profession as well as all humanity, it is best that they be denied admission to medical training. Some, and these include many of our best practitioners today, may be highly motivated by a desire for service, a hope to alleviate suffering and to save human life. A third group might include those who marvel at the wonder of nature that is man and want, more than anything, to understand more and more about this creature.

There are, undoubtedly, many more primary motivations to consider, but these latter two are enough to confuse us in planning medical education. I would like, however, to offer some evidence of the value of research in the education of both of these groups.

Let us examine first the last of my examples. A member of this group is likely to be the rugged individualist, often a nonconformist, who has an intense curiosity about natural phenomena, an ability to generate abstract ideas, and a strong desire to know. It is from this group we are most apt to develop the research men, the mature teachers, and the specialists in highly advanced fields.

To plunge them, as early as possible, into the challenging world of research in an atmosphere of freedom under the restrained guidance of a leader in their particular field of interest is, perhaps, the best educational experience we can offer. For these are minds and attitudes which need little more encouragement than a problem to confront. They are like horses bred for jumping—you need only head them toward the barrier.

The problems they discover in the laboratory will concentrate their interest on the lectures and demonstrations, especially when these offer basic material that can be applied to their research. They are inclined to be impatient with the old master who reads from the book or "Herr Doctor" who, leading them on rounds, expects his quick guess to be taken as Bible truth. But they will intensively pursue knowledge on the rounds, in the classroom, and in the library, and, while we may be hard pressed to endure their impatience and not a little hurt by their irreverence in the face of age and experience, at some future date we may well be proud to drop their names as "one of my former students" at gatherings such as this. For it undoubtedly will be one of them who will help unravel the mystery of cancer, help us stem the deteriorations of aging, help reverse the trend in mental illness.

Yet, if we cut our finger, we might not choose them first to bind it up; theirs is not an interest in easing our pain but rather an understanding of the meaning of pain itself or of the velocity of the blood flow through the cut or even of the effects of an uncleaned wound.

Again, I do not say this in criticism, for their motives are clear and honorable. Their satisfaction is not in direct service but in ultimate service. They are the sort who can give half their patients a promising drug and the other half placebos, knowing that the second half will suffer in consequence. To prove that the first half will be either helped or harmed is their satisfaction. They are best trained and kept in the laboratory. I have a feeling you might agree.

Research in Training for Direct Service

It is, of course, the group of students motivated in medicine by humanitarian considerations who raise the basic question of the value of student research in teaching. Their satisfaction is direct service. Their rewards, I might interject, are likely to be more direct and in the coin of the realm.

They have the ability to work in and with an organization and the desire to solve specific problems of immediate concern. They are not only the general practitioners but the specialists in some of the more static fields. They often have what we laymen blasphemously call a "bedside manner." Incidentally, they can do a good clean repair job on our cut finger and be genuinely sympathetic about it, too.

Why should they be subjected to the rigors of research? They usually are willing to accept the truths of the book or the old masters. It is not necessary ever to put your hand in a flame to determine that it is hot, if you will just believe your mother. Why should we force these young people to put their hands in the flame?

First of all, while it may be hard on their hands it is good for their minds. Some today say that every educated man should understand the methods of science. "Our progress in science and technology," James R. Killian has pointed out, "will be advanced by our educational success in still another area—the achievement of a high degree of scientific literacy among the rank and file of Americans." And he adds, "A man cannot be really educated in a relevant way for modern living unless he has an adequate understanding of science." It would seem to follow that a man whose ministrations are based on a science should, himself, understand its methods and that understanding of the scientific method can only come from personal experience: research.

A second reason has been suggested by the anthropologist Margaret Mead. She recently discussed the transmission of knowledge and pointed out that it has both vertical and lateral movement. The outpouring of knowledge from a wise old teacher into the minds of young people is vertical transmission, and very efficient it is if the concentration of knowledge is high and the receptacle is open. The lateral transmission of knowledge is learning together, the sharing of the pleasures of discovery between the young and old. This is even more efficient, for it requires activity on the part of the student—activity which is likely to enhance retention.

The Lebanese poet Kahlil Gibran describes great teaching thus: "A teacher does not bid you enter the house of his wisdom, but rather leads you to the threshold of your own mind." This is the process of joint learning. This is student research.

A third reason for student research in medical teaching is again motivation. Granted, the student group I now am discussing is not motivated primarily by curiosity. Yet its motives can be broadened and, I believe, bettered by research. Let me explain with a personal example:

It concerns my reading of the *Journal of Biological Chemistry.* In my laboratory days it was my habit to take each issue of that journal home, as it arrived, and spend an interesting evening looking through all the papers, reading some but scanning most. However interesting I found the papers on many subjects in this reading, I discovered that I did not thoroughly digest their contents, except when they related to my field and I read them a second time.

I am thus inclined to believe that a student can read religiously his medical textbooks and listen patiently to his medical lectures without fully comprehending what he reads or hears, unless he has had direct experience—research experience—which prompts more thorough study.

This brings me to the fourth and final value I want to cite for exposing this group to research as a part of its medical education. Understanding the methods and challenges of research will help give these people both patience to live with the inadequacies of our present knowledge and trust in the eventual success of our scientific efforts.

Our early impression gained from the surprise success of our atomic research led many to think that if we just assembled enough money and scientists in one place, we could do almost anything. Later, when we learned the tortuous and discouraging path that led to this discovery, we gained more respect for the brilliant minds which conceived the theories and the almost superhuman courage of those who brought the experiment to success.

It is this latter lesson that is important for the physician at the bedside to have learned. He can learn it best if he, himself, has faced research challenges. And with this knowledge he can be of inestimable aid to the man at the research front, for he can direct his problems and his field findings to those who can correlate and apply them, experiment on them, and perhaps improve our knowledge of them.

Let me give you an example of this sort of aid to the scientist, which many of you will recognize. I am particularly familiar with this situation because it involved a colleague in my department, Karl Paul Link.

It may not be necessary for me to explain that the University of Wisconsin is a state, land-grant institution, widely recognized for its efforts to make its unique resources as useful as possible to the people it serves. We have told the people of Wisconsin over and over again that if they have a problem that is beyond them to solve to bring it to the university. To facilitate this referral of problems, particularly in the agricultural area, we have county agents throughout the state who are trained to be alert to situations which would be benefited by scientific investigation.

As a result of all this there was unloaded on our doorstep one day one dead cow and a bucket of blood—and the serious problem of farmers in many areas of the northern plains states, sweet clover poisoning. Dr. Link's work, prompted by this problem, led him to bishydroxycoumarin (Dicumarol) and warfarin, and the rest of the story you know better than I do.

Let me stress the point, however, that it was knowledge of and faith in research that led to the solution of the farmer's problem and to subsequent medical benefits undreamed of at the time. The impetus did not come from the laboratory. Thus, I do not think it is possible to put too high a value on a medical profession trained, through research, to recognize and refer problems that science can attack and solve.

Particular Problems in Training

Now I recognize the fact that I have oversimplified the problem. I have barred from medical school those whose motives are money and treated those whose motivations are humanitarian and those motivated by curiosity as distinct groups. In medicine, particularly, we recognize that there is a considerable gray area between the blacks and whites, and, in reality, this area is rising to new prominence.

I speak now of the particular problems involved in the training of those specialists who must be called on for clinical work yet whose area of specialization is so fast-advancing that it is hardly out of the laboratory stage.

Let me select but one field out of the several in the category and discuss it briefly. Cardiovascular surgery is such a field. In work of this nature, the students often are postgraduate, the instruction highly specialized. It is not uncommon that the research team and the clinical team are of the same personnel composition. Yet it also is not uncommon for an internship to be served in such endeavor without the ultimate goal of concentration in this specific field.

In a recent symposium on experiments in medical education as they relate to cardiovascular teaching, which was part of the Fourth Conference of Cardiovascular Training Grant Program Directors, there was considerable discussion of research or project teaching. It was here concluded that the students' experience is the goal of such teaching. He learns that there is no perfectly designed experiment, and this comes as a shock to him. He gradually accepts this as being a real and necessary thing. The value is in student experience, this group stressed, not in research results. Its over-all value, this group found, is to provide the student with a critical attitude which will enable him to become a more astute observer in the evaluation of a problem.

Yet this group found it difficult to determine whether a "carry over" results. On completion of internship, it was reported, individual students refer to their project teaching participation as a favorable experience. It was admitted that under the voluntary programs the student participation is usually composed of the better type of student. It was recognized that a large percentage of these students ultimately pursue a career in academic medicine. In assessing the results of the program, it was stressed that one must have an impression of the effect of this teaching method. Dr. Robert F. Pitts of Cornell University put it this way: "It is not an impression that you have altered the attitude of a student. That his attitude has changed is not an impression; it is a reality. It is my impression that this is good."

Economic Needs in Research

Now, if I may, I would like to close on the traditional theme of all college and university presidents—money. Lectures provide economical teaching. Demonstrations, preceptorships, and clinical instruction are not too expensive, unless it is necessary to operate a hospital to provide them. But research is expensive. This is one of the reasons why some minimize it in the teaching program. But I am so convinced of its value that I feel special attention should be given to the problem of its financing.

And there are some special needs which I would like to call to your attention. Not only does research require extra space, equipment, and supplies but it removes the student from service in routine tasks and he must be replaced by a technician. Thus, extra funds are needed for the obvious research costs and, also, perhaps in the form of fellowships, to free the student from routine duties.

I call this to your attention not in preparation for passing the hat among you but rather to make you aware of this special need and to solicit your influence in meeting it. You may recall that some time ago I mentioned the word freedom in connection with the atmosphere which is necessary for productive research. Such freedom can be facilitated by unrestricted fellowship support, support which does not tie the young experimenter to a team program under a dominant director who controls research through a tight hold on the purse strings.

Again, I want to point out that the thoughts I have expressed today have been drawn from experience in a field which has only a back-door acquaintance with medicine. I hope they prompt more soundly based ideas, and I thank you for your patience with an "outsider."

RESEARCH ORIENTATION AND METHODS

CONTRIBUTION TO EDUCATIONAL OBJECTIVES OF THE BASIC MEDICAL SCIENCES

William N. Hubbard Jr., M.D., New York

At the outset, it is important to emphasize that the contribution of a research orientation to achieving the educational objectives of the basic medical sciences is no different in principle than the person's ultimate responsibility for his continuing self-education in his profession. Although the basic medical sciences present both specialized problems and particular opportunities that relate to research, they should be considered as specific examples of general problems rather than being set aside in a separate category.

Teaching Objectives

Over a three-year period, the Teaching Institutes of the Association of American Medical Colleges considered the teaching of the departments of the basic medical sciences. In each of these years efforts were made to specify the objectives which these departments set for themselves. A refreshing lack of unanimity was apparent, but it is possible to categorize two broad objectives which seem common to all of the departments. The first of these is to prepare students for the practice of medicine and the second to recruit from the student body the few students who will be the teach-

ers and investigators in the medical sciences in the future. These broad objectives have undoubtedly been stable for many decades and will continue to be so in the future. However, with the extraordinary changes that are taking place in the practice of medicine and with the tremendous growth of opportunities for teaching and research in the basic medical sciences, those concerned with the educational environment offered by the medical faculty have been reconsidering their traditional approaches to achieving their goals.

As recently as 25 years ago, only a handful of the medical faculties in the United States provided, in the basic medical sciences, an opportunity for more than a passive participation of the student in a series of didactic exercises and laboratory manipulations. The latter were commonly carried out from a detailed recipe book with the quality of the effort being judged largely by its conformity to a predictable outcome. In subsequent years there has been an exponential increase in knowledge pertinent to medicine, arising largely from research initiated in the areas of the basic medical sciences. The volume of important information is now so large that it is a manifest impossibility to present it in a comprehensive didactic fashion in the time allotted. As a result, an increasing degree of selectivity has to be exercised by teachers in choosing the material which they will present. The rapidity with which new information develops has now made it quite obvious that it is at least as important for the student to understand the process by which scientific data are reevaluated and accumulated as to master the momentary common store of knowledge.

Opportunities for the student to experience the pleasures of creative work that are inherent in seeking out scientific understanding can be more readily provided when he works independently in an area of his own interest and responsibility. This is a central educational role of research. For all students of medicine, then, these principles of instruction are the same: they must learn, against a background of common knowledge, to use their own senses in collecting enough pertinent data about a problem so that a rational hypothesis may be constructed and a soundly conceived effort taken toward the solution of that problem. To visualize and to solve problems—no two of which are precisely alike in biological systems—is equally the concern of the family physician and the research scientist. Both must have learned habits of critical inquiry and continuing scholarship that will allow them to remain creative members of a learned profession rather than simply practitioners, albeit skillful ones, of a vocation. They must be critical of their own judgment and decisions, discerning about the validity of what they read, skeptical of final conclusions, and anxiously concerned about the individuality of the problems to be solved. In short, they must learn to be scientific physicians, whether their work is at the bedside or in the laboratory. The setting in which these goals can be accomplished is compounded of students of excellence and faculty of distinction working in an atmosphere of scientific inquiry, critical self-appraisal, and independent scholarship. The intellectual discipline of accurate observation, logical deduction, adequate verification, and final generalization is the common goal.

Student Participation

The active participation of the student and his developing sense of individual responsibility for his own work are requisites of success in achieving the objectives of education in the basic medical sciences. The student must therefore assume responsibility in using the opportunities afforded by the faculty for self-development. Cardinal Newman in his lectures on "The Idea of a University" has emphasized that 'this kind of cultivation of the intellect is in itself an appropriate goal, just as the tending of the body with a simple view to its general health is acceptable. On the other hand, as general health is fruitful only as it precedes useful labor, so the trained intellect in its chosen field of special competence is fruitful by being able to think and reason, to compare and discriminate, to analyze with refined taste, and to formulate general judgments.

The zest for individual excellence is difficult to acquire under any circumstances but almost impossible where the student is bound to conformity to a too rigid curriculum. The quality of rational, informed skepticism which Santayana has called the "chastity of the intellect" is a natural outgrowth of efforts to pursue rigorously one's own interests in the sciences. Whitehead has suggested that the most austere of all mental qualities—a sense for style—can be recognized by the enthusiasm of attainment coupled with the discipline of restraint. The capacity of a person to love a subject for itself is the manifestation of achievement of style in that area. This almost moral sense of the intellect is the product of specialized study, and it is the exclusive privilege of the expert. The pride of craftsmanship that is developed is a continuing insurance of the maintenance of one's own individual standards of excellence.

Actually, the functions of transmittal of information and training in research techniques that are carried forward in medical schools could be performed at a cheaper rate separately from these expensive institutions. Books are cheap, and the system of apprenticeship is well understood. The justification for a university ideal is, as Whitehead has emphasized, in that it preserves the connection between knowledge and the zest for life. The university not only imparts information but imparts it imaginatively and critically. This quality of imagination is a contagious disease, to be disciplined by knowledge and the habit of scholarship to become responsible scientific inquiry. The development of a scientific style is therefore one of the particular contributions that research efforts can make in the education of future medical scientists. If a medical scientist is a scientifically trained physician, then there is no difference in this regard between good medical practitioners and good medical scientists; the more scientific the inquiry of the physician about his patient, the better practitioner he is. There need be no conflict between the art and the science of medicine, since noble behavior is not diluted by scientific knowledge and good practice depends on both of them.

Basic Medical Sciences

One of the most serious problems confronting medical education today is the decreasing number of physicians who are entering careers in the basic medical sciences. In spite of the rapid advances in certain areas of medical science in recent decades, the fact remains that medicine stands today only at the threshold of its development as one of the biological sciences. Unsolved problems of crucial importance concerning man and his diseases are still to be approached in all fields of medicine. Because of this, there is an increasingly urgent need for talented persons to take up careers of investigation and teaching in medicine. At the present time, the need is not being met. On the contrary, the number of medical school graduates in training for such careers seriously threatens, through shortage, the continuing progress of medicine. The spirit of adventure that is inherent in a search for understanding must be made available to the student if he is to sense the satisfactions of an academic career. Through participation in research activities he can personalize the growth of knowledge rather than look on it as some extraneous phenomenon. By participating in research he learns at first hand the importance of biological variation. He acquires an ability to deal rationally with variables in terms of mathematical probability. Simultaneously, he learns of the ever-present opportunities for improved understanding.

It seems quite clear that if a student learns from the basic medical sciences only the facts and skills that are preselected for him by the organization of the curriculum there is little motivation for him to consider a career in the basic medical sciences or, for that matter, to acquire the scientific style which could later distinguish him as a clinician. It has therefore become useful to provide a degree of flexibility in the medical curriculum and to give an opportunity for independent study and research training in areas of the students' own interests, in addition to maintaining the highest standards that insure a student to be fit for these independent intellectual enterprises. As Dr. Vernon Lippard has written of the program at Yale University, it is fundamental in the concept that the student is a mature individual, that he is strongly motivated to learn, and that he requires guidance and stimulation rather than compulsion or competition for a relative class standing. Equally basic is the concept that if a student is given unusual privileges he must assume more than usual responsibility for his education. Although these views were expressed in reference to the medical student, they could apply with equal emphasis to the mature clinician and the investigator.

Specific Research Program

In the past decade many medical faculties have increased their emphasis on research, following the lead of those in which the emphasis on research is traditional. The presence of active research efforts by the faculty has provided the opportunity for experience in research increasingly enjoyed by medical students. Rather than attempt a summary of programs in student research, let me describe the outline in a single school, emphasizing that it is cited as an example of convenience rather than implying that the opportunities are unique.

I refer to the New York University College of Medicine. For a few selected college students interested in research, summer laboratory experience at the medical school is provided. Generally, these are talented students who have not fully decided on their careers and who may be attracted to medicine by becoming more familiar with its foundations. Similarly, the summer is a time when large numbers of students in the four years of medical school undertake independent work. The student is required to prepare a short research protocol and have it endorsed by his potential sponsor, who is a senior investigator. The applications are reviewed by a faculty group and modest stipends awarded on the basis of merit. For those few students who have undertaken significant problems in research and who are seriously interested in an academic career, a fellowship year in full-time research is provided. The merit of the candidates determines the number offered, but it is small.

Throughout the first two years the students may elect to participate in an honors program. This consists of a series of weekly lectures and related seminars given on Saturday mornings. The speakers are persons distinguished for their research activities in biology and biochemistry related to medicine. There are also journal clubs for students, with an elected faculty preceptor, that meet twice a month in the evening. Faculty research advisors are also available to help the student initiate his own independent work. Since this program is voluntary and extracurricular and since its work demands are rigorous, the self-selection by students is striking.

In the first year—at the completion of the regular anatomy course—a special series of lecture and laboratory periods are devoted to current research approaches in anatomy. Electron microscopy, cytochemistry, tissue culture, and histochemistry are included. Similarly, in biochemistry a special series is given after a condensed basic course has been presented. This group of lectures and laboratory exercises introduces in some detail problems of protein characterization, enzyme chemistry and nucleoprotein metabolism. In pathology there are about a dozen two-hour periods where students in very small groups have demonstration-seminars in the laboratories of the individual investigators in the department. Here they see and handle the actual "bench work" as well as being able to discuss the problems with the investigator.

In the fourth year, there is a four-month block of elective time, which, with preceding vacation periods, can be extended to seven or eight months, when the student may pursue uninterrupted research without omitting any of the regular curriculum. By use of all vacation and elective time, 11 calendar months of research may be included in the four calendar years of the curriculum. This allows for that most important phase of encouragement of youthful imagination without demanding a premature commitment to a career in either practice or academic medicine. The particular role of research in the basic medical sciences is, then, an essential part of the development of the medical scientist, whether he be scientific practitioner or scientific investigator.

CONTRIBUTION OF RESEARCH ORIENTATION AND METHODS TO EDUCATIONAL OBJECTIVES OF CLINICAL SCIENCES

Nathan A. Womack, M.D., Chapel Hill, N. C.

Most students enter medical school with an idealism often not expressed but directed toward human service. With this is also frequently coupled a deep-seated curiosity as to the nature of biological phenomena and an intent, in some vague way, to elucidate them further. The humane idealism needs to be fostered certainly, and this is not difficult. A critical curiosity, however, is not at all easy to direct; nevertheless, unless we can direct the ordinary student into the development of a critical frame of mind, this curiosity will atrophy and the progress of medicine will be slow indeed.

I thus find this topic that I have been invited to discuss an intriguing one—this relationship between experimental methods and the development of the physician—for it introduces a possible way of encouraging this curiosity. It would hardly have been feasible, even a few years ago, to consider giving time to the problem of research and the experimental laboratory in the clinical years of undergraduate education. Just a short while back the experimental laboratory was not for the student who was a sound clinician but rather for the student who often showed a lack of the practical yet was able to make excellent grades in his subjects. To serve as a laboratory assistant to an able investigator in the preclinical sciences was often sought for, it is true, but equally as often the stipend rather than the intellectual opportunity was a very strong motive.

For the student who was to be a good clinician, the experimental laboratory was considered by some actually to be a detriment, since it tended to warp clinical judgment. In such an environment one saw the problem as it concerned an experimental animal or as it existed in the chemical laboratory, not as it manifested itself at the bedside.

We find ourselves now concerned with the wisdom of acquainting the undergraduate student with the experimental laboratory and in this consideration with the undergraduate during his third and fourth years of medical school education—just those periods in which most schools provide their teaching in clinical medicine. We who for some time now have made a fetish of bedside teaching are actually suggesting that this be diluted with a participation by the student in experimental medicine, or at least an understanding of the methodology of experimental medicine, for a dilution will be necessary. We cannot just add such an experience to the curriculum, for there is no longer any extra time in the curriculum. We naturally view such radical change with suspicion.

Bedside Teaching

We have lived with the philosophy of bedside teaching for so long now that its very concept has become sacrosanct. It is true that years back, when

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 9, 1959.

this form of pedagogy was establishing itself, it had its own troubles in superseding the lecture. Many times the concept of bedside teaching was taken perhaps too literally, and groups of 20 or 30 students were distributed around a patient's bed while the teacher percussed the dimensions of the heart of his patient or tried to demonstrate a soft presystolic murmur to an unappreciative audience. "Old Shifting Dulness" he was called, and he taught clinical medicine in many a hospital ward, a sort of Mr. Chips, completely unequipped to stand the onslaught that was to come from the clinical laboratory and its effect on patient care.

At other times, though, this Mr. Chips was an able clinician and an inspired teacher, who would listen to the clinical history given by the student, make a brief and accurate examination of the patient, and then present a clear and logical analysis of the events that were transpiring within the patient. Observation was often so accurate and so complete that the deductive method needed hardly to be brought into play. At other times, objective manifestations were scant and here deduction played a more important role. Occasionally the student saw a rebellious mind at play—one unwilling to accept a relationship between phenomena as causative, when that acceptance often had become honored by time and usage. With the good teacher always the student found a thinking, logical mind capable of inquiry and also capable of directing that inquiry even though the methods used might be as simple as those of William Harvey. Most students tend to direct their interests and their methods of approach toward the solution of a problem in the same direction as does the teacher who affords them stimulation. This good teacher, then, in proportion to his abilities and to the time he found available for his teaching, performed well, because many of his students performed well. Many of us are thinking just now of men who fell into that category. Many of his students, however, not having the faculty of astute observation, relied more on deductions and assumptions, and the practice of medicine too often concerned itself with the recognition of clinical syndromes and an empirical therapy.

There were times when even this good teacher was unable to adjust to rapidly changing social and economic trends that were affecting his patient, the relation of the illness to the patient's family and to his community, and, again, the rapid progress made by the clinical laboratory. Change was necessary, and the change that has come, most of us will admit, has been an improvement. Perhaps, however, with a sense of nostalgia, we miss something that these men had to offer, for what they lacked in milliequivalents they compensated for in an ability to observe and to think. They were individuals and, as individuals, would not have been tolerant of group thinking and group research.

Decline in Clinical Observation

Why has the introduction of the widespread use of the clinical laboratory, with its more accurate tools, tended to reduce the form and effect of such brilliant clinical teachers in our faculties? Fundamentally, I think, the major effect has been on clinical observation. Clinical medicine could not become a science until its phenomena could be measured, could be quantitated. As an example may be cited the ability to determine the amount of sugar in the blood with the advent of the discovery of insulin and its use in the treatment of diabetes or the determination of the state of renal function by the measurement of the amount of certain substances in the blood plasma. There are many others, of course. Crude observations were not enough. To note that a patient presented pallor was inadequate in the understanding and treatment of anemia. Inspection, palpation, and auscultation were not thrown into discard, but the acuity of their use has been less evident since the introduction of laboratory methods. We may regret this, but at the same time I think we must recognize that it had to occur. Instruments more accurate than the eye and more subtle than the touch have necessarily taken the place of cruder methods of observation. Clinical observation then being less important became less accurate. The physical examination deteriorated until one now so often sees it on the hospital record existing as a jumble of unintelligible abbreviations.

As different tests began to be developed, the diagnostic tools were literally removed from the hands of the diagnostician and placed in the hands of technical assistants. The laboratory has not been free from pedagogic fault. Too often it seems the student now studies the diagnostic problems that his patient presents through the medium of a signed requisition. The radiologist on request will measure the size of the heart for him, and the cardiologist will present him not only with a picture of the rhythm but with one that will show the electric conductivity as it exists in various portions of the heart. He will even take a picture of the murmurs if any exist or measure the diameter of the mitral aperture if there is a degree of stenosis. The radiologist will diagnose for the student the nature and the extent of pulmonary disease with an accuracy often beyond that which the student or his teacher can obtain with the stethoscope, and this once ubiquitous tool of the internist now finds itself chiefly in the pocket of the surgeon, who notes its chief value in listening to the musical gurgles of gas as it fights its way downward through the recently traumatized intestinal tract. Even though a surgeon, I cannot but at times express regret at the lowly estate to which this once treasured instrument has fallen.

In the laboratory analysis of substances present in the blood, either naturally or from the use of certain functional tests, a new vernacular is developing. One now hears the expression "the patient's chemistries" were normal or a "spectrum" of liver function tests was performed, or the patient is now "in balance." It is not unusual to have many of these analyses made as a "routine" procedure. As such they require no discriminating thought. One merely needs to collect and appraise the results. I grant a modicum of exaggeration.

Such use of the laboratory has led to greater demands for diagnostic procedures to be performed, and this in turn has led to greater use of the specially trained technician. Too few students today know the vagaries of the techniques that are used in performing the tests that they demand, and no one now expects them to. More and more we move into a period in which the accuracy of diagnosis of a patient's disease rests in the hands of others than his physician.

Before I am accused of being too partial in directing attention toward the diagnostic methods learned in general medicine that tend to permit others to usurp diagnostic authority, let me add quickly that the surgeon is in no way different. An example is seen in his approach toward a patient with a lump in her breast. In most of the instances this patient finds the lump first. When she consults her surgeon, he does not even have to suspect cancer; she has done it for him. He places her in a hospital and removes the lesion in order to establish a diagnosis. It is true that a description of the physical characteristics is recorded on the clinical record, but the mass is destined for removal regardless of the diagnosis. Once the mass is excised, the surgeon may examine it if he wishes but the diagnosis is not official until a pathologist performs a frozen section and tells him the diagnosis. It makes no difference that most surgeons can recognize a cancer of the breast when they cut it out and look at it. The hospital must provide that pathologist's service, and a tissue committee sees that the surgeon uses it. As a result, morbid anatomy ceases to have as rigorous a position in the clinical years as it formerly did.

These tests have piled one on another until it is difficult at times to evaluate their meaning. There is no need to cite other instances. They are familiar to us all. We are equally familiar with the fact that the utilization of these procedures and the expert personnel required in their elaboration has also given us a diagnostic accuracy and a therapeutic achievement that has been thrilling to see unfold. We may wish to use these procedures more wisely and with more thought. We may object to the inspection by outside agencies who wish to make sure that we are using them. However, none of us would care to practice medicine very long without them.

Nevertheless, the ability to take an accurate history, to observe the physical appearance of the patient with utmost detail, and then to analyze the significance of this information is losing its acuity. In its place we are developing a mechanization of the art of diagnosis and a therapy by formula. We see an apparent lessening of the need for critical reasoning because of the utilization of an instrumentation often too complex for the student to master or, at times, even understand. We are thus confronted with the paradox of retaining and even continuing to expand the fine accomplishments of laboratory medicine and yet at the same time fostering in our student an attitude of observation, doubt, and inquiry that he formerly received from bedside observation and teaching. But this paradox can be solved, for many have done it.

Pedagogic Value of the Experimental Laboratory

Undoubtedly the best clinical teaching that we encounter or our wards today is coming from those men who have been able to relate the laboratory to the patient. It is because of this very fact, I think, that our subject today is important, for these men have one thing in common. Not only have they studied the sick individual with all of his numerous problems but they have been more than casual participants in understanding the analytical methods of the laboratory. They have asked questions and sought the answers by experimentation. To do this, the tools and tests of the laboratory have been only a means, not the ultimate goal. Why then would not this educational pattern of the good teacher be a good experience for the student? Would this not be a good way of solving the pedagogic dilemma in which we have found ourselves during the clinical years of undergraduate education? Perhaps yes, if it could be done well. This would make it possible to encourage the student to ask a question and then aid him in developing a methodology by which the question might be answered. Certainly the ability to ask and then to answer such a question will be an index of the maturity of the student's education. But will a period in the experimental laboratory really do this, and, if so, how can it be brought about?

Under consideration here is not the value of good clinical research but rather its value in helping to develop an inquiring mind in the average medical student. I doubt if such experience will develop much originality. It is conceivable that the student may bring to such a study original and well-thought-out ideas or that similar ideas may develop as he elaborates on a problem supplied him by someone else. Such will, as a general rule, be beyond the ability of the average junior or senior medical student. We shall not be considering, therefore, the idea of inserting into our clinical curriculum a brief period devoted to discovery, for the chances are that while originality would be cherished it could not be taught.

The value that such a discipline would have to offer then must relate to its methodology. This methodology is complex and, in accent, will vary from time to time. It is fundamentally concerned with imagination, reasoning, observation, and understanding, and these certainly are qualities we would like to develop in our students. It would be well, then, if our student entered this study with an academic background that allowed the free use of epistomological rules. So few of our students do, however. Most of them have spent far too much of their time before entering medical school in accumulating scientific facts or have taken their majors far afield—in music or in history. Desirable as this knowledge of formal logic may be, the lack of it should not pose an insuperable hurdle. Often the student who has had a preparatory background in the liberal arts will have adequate experience in the use of formal reasoning to understand the nature of the goal and the principles involved. This being true, the research problem will best be set up with student participation and not prepared in detail for him. Here the student will come face to face with the nature of research and the ability and character of his teacher.

By clinical research I am not concerned here with retrospective studies in the record room, such as the counting of the number of people who have survived for a period of five years or more after a particular therapy. I am also not thinking of the "case report with a review of the literature." Enough data of this sort have accumulated to satisfy even the dust of Francis Bacon. I am thinking of research as it applies to answering a question by a well-devised experiment. Such research has been described in many ways. I like a recent definition of Bernard Greenberg's, "a burning yearning for learning." If the first letter of the last word is omitted, one sees clearly the common motive for violation of the essence of research. Too often, research studies become the legal tender of academic life. There are deans and even faculty committees who use the number of papers published as an index for academic promotion. We teachers are critical of this; we even become cynical about it but, when asked to serve on a similar committee, find ourselves seriously considering the same unit of measurement. The annual departmental report is often mute testimony of that department's scientific interest and motives. The late Professor Robert Bensley made a point of insisting that it was of little importance who first did a piece of work or who was first to report it. The important thing was always "is it true." A student introduced into an atmosphere where something less prevails will be injured by the experience. Besides a good intellectual background then, he needs a teacher and a guide, for here he must see nothing but the best in scientific morality.

It is difficult to imagine a more valuable experience in self-criticism than that of designing an experiment under wise guidance that would give valid results regardless of their nature. In setting up an experiment, in determining the number of observations and the nature of the control, biostatistical methods are a necessity. Experimental design must follow fairly rigid rules, or else observations become untrustworthy or irrelevant. Often the recipient of jokes by the "practical" investigator, the biostatistician has been a patient soul. For a long time he was ignored by the clinical investigator, but, as evidence began to accumulate as to the use of formal statistical methods in the evaluation of data, a change in attitude began to take place. Many schools now even have a course given in biostatistics. This consists, as a rule, of only a few hours of instruction, it is true, and generally it is given in the preclinical years in order not to take time away from sound clinical experience. Perhaps eventually it will be taught in the clinical years and papers that have been published in some of our clinical journals given students for statistical analysis as exercises in critical judgment. If this were done, it undoubtedly would have a beneficent effect on certain editorial policies. It would have an equally good effect on medical education during the clinical years. There is probably no better critical experience than that of studying published clinical reports from this vantage point.

Having planned the experiment with the type of observations to be made, the student must now make these observations. It will be recalled that Claude Bernard felt that the observer must be unprejudiced and passive. Only when he becomes the experimenter is he allowed to be the active questioner of nature. Prejudicial observations have meant a fatal ending to many careers. Fortunately, we have reached a position today when it is a very simple thing to obtain such "passive" observations. Such is the value of electronic devices. Observations can be made speedily, accurately, and repetitively —provided that the proper instrument is used, that it is well calibrated, and that its mechanism is understood. It is of little value to measure "that which one knoweth not." It is essential, therefore, that the investigator be familiar with the instruments used in making his observations. He cannot safely rely on a technician to supply him with his data unless he can supervise the work of the technician. For the student to be placed on an experimental problem, so designed that the observations are complex and must be made by an expert employed with funds obtained from a project grant, may result in the answer to a question, but it will not be a good exercise in critical judgment. The type of experiment on which the student works must therefore have definite limitations. So many students, not being seasoned investigators, have what amounts to a saintly disregard for such detail in experimentation. They demand that they be allowed the privilege of great discovery. It is up to us to acquaint them in the beginning with the cost.

Besides being familiar with the design of his experiment and the instruments and techniques with which his observations are to be made, the student must also have a thorough knowledge of the background of his problem, of the work that others have done relating to it, and of the accuracy of their conclusions. He must have read, and read in such a way that he has explored, many collateral fields. He must know how to catalogue his reading, discarding the irrelevant and preserving the important. He must know how to record his observations so completely that no experiment need be repeated and that when his data are assembled a valid conclusion can be made. This will take time. It is not a job for odd moments.

These are rigorous rules that I have outlined, and intentionally so. A slovenly performance by the student in the experimental laboratory would defeat the very purpose for which the experience is being designed. For a student to work in a laboratory during the summer months with a stipend that is generous, on a problem that is vague and without adequate supervision, is not enough. The student must be taught in the experimental laboratory with a care equal to that with which he is taught on the wards. Just now there is a real shortage in clinical teachers who are familiar enough with the experimental laboratory to do the work well. Too many of our clinical teachers are products of a graduate curriculum specified for them by their specialty boards. Such an experience in research is no concern of a specialty board. Most schools have a few such men, however, and just now there seems to be a preponderance of these in departments of internal medicine. If the experiment is a limited one, a beginning can be made. Obviously, students would have to be selected carefully. Perhaps this is well, for at present few schools have entire classes in their clinical years that would be receptive to such an experience as being preferable to that spent in some clinical endeavor. Nothing could be more detrimental than to have a coercive approach.

A number of our schools are already proceeding with this curricular experience in spite of these obvious difficulties. Enthusiastic students with good minds are already coming under the tutelage of able clinical investigators during their summer months and during elective periods. The result seems to be well worthwhile. It is highly likely that the practice will gather momentum and that it in itself will make facilities more readily available. Needed will be able students and good teachers with available time, space, and equipment. Just now no school has enough of these, and therefore an evolutionary approach is mandatory. It promises to be a notable addition to the curriculum of our clinical years, but it cannot be brought about by simply assigning a block of time for research during this clinical period, as some have thought possible.

THE ROLE OF RESEARCH IN GRADUATE MEDICAL EDUCATION

James A. Campbell, M.D., Chicago

The increasing significance of the role of research in the education of all physicians is readily apparent, and the value of research in teaching the scientific method and extending its war against empiricism needs little further apology. Its usefulness in stimulating curiosity and evaluating data is true at any time in a physician's career—whether it be as student, graduate, or practitioner. What, then, are the questions to be raised concerning the proper place of research which are peculiar to graduate medical education? How is graduate medical education different from undergraduate medical instruction? Perhaps a set of answers to this latter question might help in part to answer the former.

Establishment of Research Orientation

"Undergraduate experience," according to Darley, "is aimed at developing the fundamental principles applicable to the whole body of medical knowledge, at establishing habits of reasoned and critical judgement of evidence and experience, and at developing the ability to use these principles and judgments wisely in solving problems of health and disease."[1] The graduate years are reserved for undertaking "to become as proficient as possible in the complete, detailed, systematic body of knowledge and in the techniques and the judgements required to excel in the one discipline of his [the student's] choice."

In the graduate years, then, it becomes evident that an intense effort to develop more and more independent patient responsibility is one of the primary components of the graduate experience and that an increase in the skills of applying knowledge becomes essential. The young graduate physician becomes more and more a "doer" as he continues his scholarly attitudes.

If it is felt by undergraduate instructors that the experimental method is one of the prime effectors of "establishing habits of reasoned and critical

---

Professor of Medicine, University of Illinois College of Medicine, and Chairman, Department of Medicine, Presbyterian-St. Luke's Hospital.

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 9, 1959.

judgment of evidence," then it might well follow, as Dr. Vernon Lippard has described, that research would be an assignment and a requirement for receiving the M.D. degree without regard to whether the student was interested in or capable of creative effort. Since the undergraduate medical years are particularly formative ones, this concept may be valid. At any rate, those people who concern themselves with the programs of graduate medical education seem to me to have the right to expect that the undergraduate medical students come to them prepared for their graduate experience inculcated with the spirit of the scientific method and eager to apply it in increasingly independent action in planning and carrying out both diagnostic and therapeutic goals.

If this be true, then at the graduate level research should not be forced but merely fostered. This is an attitude which I would like to believe is not only conducive to good education but also helpful in producing better research. We must give graduate students in medicine, that is, house officers in their internships and residencies (since this obviously does not obtain with respect to research fellowships or the like), a chance to make a mistake of choice in this area as well as decision in the area of their clinical graduate training. They need and should have consultations, but they need to become more and more independent in medical development.

I think I agree with the statement of Lewis[2]: "There is no doubt of the value of research in the nurture of the critical mind; however, I think we are unrealistic if we fail to recognize that only a few have real aptitude and interest in investigation." Does it really seem profitable or logical for a young man who does not have that interest and aptitude to spend a year during which he functions intellectually not far above the level of a technician?

On the other hand, I do sincerely believe that research must be encouraged and that graduate medical educational programs must be geared to stimulate the participants either to continue or to initiate investigative programs of some nature relevant to their own discovery of a problem which warrants solving by first-hand contact with it during the course of their training. Also, research time must be planned for in the residency programs if a person elects to spend a significant period in this fashion. The replacement of the classic pyramidal pattern to the chief residency by the block type of structure has done a great deal to encourage the exploration of a given medical area through the use of a research discipline. It should be stated for completeness that not all students who may elect to try investigation as a method of continuing their education will achieve research results worth much to anyone other than the person who did the work, who, after all, is a most important person.

Research Methods

What are some of the opportunities whereby research methods may play a significant role in graduate education? First of all, the literal use of the word "research" may be exactly what some house officer needs to give him a new chart by which to sail. By this, of course, I mean emphasizing and reemphasizing the one fundamental investigative tool which is all too frequently underestimated, and that is a search of the literature. This is a firm building block of any investigation and it is also an equally important contributor in any continuing education, for it requires a well-developed and perhaps well-disciplined curiosity to be successful in either.

Two things are involved in searching the literature. First, it makes certain that the potential investigator is not merely satisfied to keep busy by working with his hands. Parkinson's[3] law holds for the laboratory as well as for the administrative office. The law in part states that work expands so as to fill the time available for its completion. Second, the investigator may find that his experiment has already been performed. This is doubly comforting on second if not on first thought. If the observations have previously been made, it has saved time and effort (unless he wants to confirm them) of performing the study and it requires critical evaluation of techniques, interpretation, and conclusions before accepting it. It also indicates that someone else thought enough of his idea to invest talent and energy in it, which may stimulate him further. However, it may take considerable introspection before this state is reached.

While the prosaic technique of reviewing the literature is being emphasized, I should like to point out that, obligingly, Castle[4] recently has mentioned the "case report" in a favorable light. He writes, "As with the modern clinical investigator, a hazard run by the busy physician is that he will forget the basic orientation value of his senses. Complex apparatus is not without its disadvantages to the mental activity of the clinical investigator; and without a clear history, a careful physical examination, and simple laboratory studies, the physician may also become lost in a wood in which he sees only the trees. Worse, he may lose the curiosity that urges him onward to a better understanding of disease and of his patients. This is the danger when the dizzy round of the immediate and the urgent becomes too pressing. Then is the occasion for time out for a refresher course or for the preparation of a case report with the help of the medical library where there is sanctuary and sustenance for the hard pressed mind."

This preservation of the curiosity by contemplation and study is an ancient process highly revered. "Curiosity," Castle says, "is an autocatalytic process. More facts come to the attention of the curious observer, and so more and often unexpected data accumulate to be contemplated in search of significant relations. Now, the most difficult problem in medical education is not how to become but how to remain educated in a rapidly changing scientific world. I can think of nothing more likely than intellectual curiosity to provide the necessary growth and development of the individual's knowledge and effectiveness."

A second approach to encourage the possibly non-research-oriented house officer to consider the role of research in his graduate education has been his exposure to research laboratory techniques which have been adopted as perhaps a relatively recent addition to the armamentariums of standard good practice. A rotation of a few months through a modern clinical cardiorespiratory laboratory may be sufficient to whet the appetite both for improved clinical acumen and for scholarship. The results of such contact are immediately apparent on the wards, and the increased number of cardiac research fellows attracted by this technique has been demonstrated amply throughout the United States. The primary proposition is not, however, how to get more research done, but how it may apply to the learning process at the graduate level.

In the same category is the so-called basic science laboratory assignment, usually in pathology, although more recently in biochemistry. This has long been tried as a stimulus for scholarship and, in turn, for an added dividend at the training level. Degree programs which have been developed with this used for a backdrop have been in successful operation for a number of years. Pruitt[5] reported on this to this Congress in 1956. One point which he emphasized quite properly was the production of a scholarly thesis as an indication of effective work, but he pointed out that, whereas the assignment to the laboratory was arbitrary, the exploration of the unknown was an optional derivative of the experience.

I would be remiss if I did not mention that, in any of the guises of introducing graduate students to the laboratory areas, it is apparent that they are being thrown into contact with men who usually have some inclination in the direction of research and without whose enthusiasm, instruction, and counsel the time spent in the laboratory would be similar to that spent as a house officer on a ward without a visiting physician.

If any of the various strategems have been successful in stimulating house officers to scholarship, it would seem valid to insist that an appropriate amount of free time be allowed during a residency for carrying out any soundly conceived research program. In this concept it is convenient to have men and facilities in one's own unit to support the research resident through a significant period. If this is not possible it still seems a wise expenditure of time and funds to attempt to find an opportunity elsewhere for such a person. At this point the secondary gains of such a venture to the staff and house officers would seem to justify this approach.

House Officer Education

There is one other possibility to consider: that in which a student has gone through the undergraduate medical curriculum, has definitely decided on a career in the fundamental sciences, and now is curious about what the role of house officer education is in basic research. I believe this type of experience is often as valuable to the productive career of a basic scientist as research experience is to a clinician. For one thing, I would encourage such a house officer to become actively engaged in some pure clinical research in which human beings must be studied with care, competence, and compassion —a study in which the patient's signing out two days early would "ruin" either the test or the control period. I would hope through this means not only to bring him into contact with new information and discovery but also to demonstrate that there is bad laboratory research as well as good and that there is good clinical research as well as bad. I would hope that he might learn that experiment in both clinical and laboratory research is perilous. One other thing which I would expect that he might learn in this period of graduate medical education is that "while planned experiments," as John P. Peters once suggested, "afford the advantages of voluntary control, the genius of man cannot yet compete with the capricious ingenuity of nature, which has performed upon patients experiments as yet beyond the technique of the physiologist. The science-for-science's-sake and the you-never-can-tell-where-it-will-lead philosophy can be overworked. If clinical investigators need to live down their somewhat shady past (as once was pointed out) laboratory investigators may need to live down their more pretentious present. The number of free-wheeling clinical investigators is probably not greater than the number of test-tube investigators 'becalmed in the doldrums of techniques and mechanisms.' The individuals of genius are perhaps as rare in one group as in the other."

The impact of investigators on house staff education and the participation in research may be profitable and exciting at any time in graduate medical training, and the close contact with patients and their problems can sober the most enthusiastic scientist with the thought of how much more there is for everyone to know and do.

RESEARCH AND THE TEACHER OF MEDICINE

Isidore Snapper, M.D., Brooklyn, N. Y.

There can be no doubt that an effective teacher of medicine must be deeply interested in medical research. The faculties of the medical schools have understood this for many centuries. Every time one or more clinical chairs became vacant, the schools searched for new incumbents among physicians or surgeons who were (1) outstanding teachers, (2) experts in the clinical field they were going to teach, and (3) well-trained experimenters who had made contributions to the scientific aspects of their own fields of medicine. In different schools different degrees of emphasis have been placed on these three requirements, and in certain medical schools the trustees and overseers may have been too interested in whether the professor or the associate professors taught sufficiently and efficiently. In modern times it seems as if this emphasis has changed. In many areas interest in discoveries in medical research has taken the place of interest in efficient teaching.

The teacher of medicine must be well versed in research methods and in the scientific approach to clinical problems because the medical student of today will probably still practice medicine in the year 2000 A. D. This means that our medical schools must provide education which will cover not only the year of graduation but also the four following decades.

Through the ages the progress of medicine has always been rapid, and it can safely be predicted that the knowledge of today will be old-fashioned and even obsolete in 40 years. Many of our contemporaries feel that this historically well-tested experience is not valid anymore. They contend that in our times the progress of medicine has been so much faster and so much more fundamental than in any other comparable period that our knowledge of today is here to stay. However, for many centuries the medical scientists have cherished this erroneous concept.

Every generation of physicians has assumed that at last the stone of the philosophers, the arcanum, the panacea, has been discovered. Boerhaave, Benjamin Rush, Charcot, Osler, and many others extolled the world-shaking and revolutionary innovations which during their lifetimes had—in their eyes—fundamentally changed the aspect of medical science. William Osler wrote in 1902: "Never has the outlook for the profession been brighter. Everywhere, the physician is better trained and better equipped than he was 25 years ago. Disease is understood more thoroughly, studied more carefully and treated more skillfully. . . . Diseases familiar to our fathers and our grandfathers have disappeared, the death rate from others is falling to the vanishing point and the public health measures have lessened the sorrows and brightened the lives of millions."

The most enthusiastic medical neophyte could not sing the praise of 1959 in words more exalted than those Osler used in 1902. To Osler the progress of medicine in 1902 appeared just as revolutionary as the new developments in medicine appear to us today. It seems hardly possible that medicine is shaken only occasionally by revolutions, and there is no doubt that our knowledge of today will appear in the year 2000 as the medicine of Osler's time appears to us today.

The graduates of 1959 will only be well prepared for the medicine of the year 2000 if during their training in the medical school basic medical concepts are kept in the foreground. Since in our American medical colleges experimental medicine and the explanation of the pathogenesis of medical symptoms and signs are emphasized, we can be satisfied that our students are well qualified to understand new aspects of medicine which are bound to be developed in the future.

At the same time, medical education must also provide thorough training in the medicine of today. The fact that the problem of research and the teacher of medicine has been chosen as a topic for today seems to indicate that qualms are being felt about the effectiveness of certain aspects of our teaching. In other words, we have gathered here today to find fault with ourselves in order to strengthen our education by correcting our weaknesses.

Vulnerable Spots in the Educational System

Actually, the opinion has been voiced that two potentially vulnerable spots may have developed in our medical educational system. The ensuing damage, I hastily add, is, as the final analysis will reveal, well compensated, and the ultimate outcome will remain highly satisfactory if a few reorganizations can be decided on.

First, the dangers of overemphasis on research in medical education should not be underestimated, even if untold advantages accrue to the teacher in medicine who is also interested in and occupied with research. Clinical medicine can be defined as the application of medical knowledge to the diagnostic, therapeutic, prognostic, and sociological

---

Director of Medicine and Medical Education, Beth-El Hospital.

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 9, 1959.

problems of one special patient or of a group of patients. In the estimation of most of the experienced diagnosticians I consulted, more than 75% of the knowledge which a good clinician must at all times have at the tips of his fingers is purely empirical. A few examples may suffice: the leukopenia in typhoid, the thrombopenia in relapsing fever, the dorsal flexion of the big toe in the presence or damage to the pyramidal tract, Kussmaul's breathing in diabetic ketosis, the localization of the tuberculous meningitis at the base and of the meningitis caused by Neisseria meningitidis and that caused by Diplococcus pneumoniae at the convexity of the brain, the peracute start and the acute crisis in lobar pneumonia, the prevalence of influenza bacilli in bronchiectasis, the tendency of bronchial tumors to metastasize to the brain, the predisposition of the adrenals as the site of metastasis of certain malignant tumors, the development of clubbing of fingers in ulcerative colitis, subacute endocarditis, and other diseases, the early destruction of the intervertebral disks in inflammatory diseases of the spine in contrast to the conservation of the disk in metastatic vertebral destruction, and the preference of gout to attack the metatarsophalangeal joint of the foot. These are merely an infinitesimal fraction of the innumerable number of facts of great clinical importance which have to be learned by rote because until now all efforts to find a satisfactory explanation have failed.

Although the progress of medicine will mainly depend on research and experimentation, the fact remains that 75% of the knowledge of the clinicians can only be acquired by humble empirical observations at the bedside under the guidance of experienced clinicians. This part of medical education may suffer in certain schools where the departments of medicine are directed by full-time scientists who largely believe in "reduction in the degree of empiricism" and consequently have only scant interest in empirical medical knowledge without which the clinician cannot do his work.

Second, the short curriculum in American medical schools is also a reason for concern. In 1917, the curriculum lasted for four years, although in most European countries medical education was extended to a period of six to eight years. Now, more than 40 years later, in spite of the tremendous expansion of medical knowledge, our curriculum is still limited to four years. It seems to be generally accepted that even today this four-year curriculum is just as sufficient as it was in 1917 because our future medical students receive careful premedical training during the three to four years of their college education. This argument is not valid.

Today there is general agreement that, with a few exceptions, the training in the high schools of the United States is insufficient for future university students. For all practical purposes the three to four years in college only enable the medical students to obtain the knowledge which they should have obtained in a high school of good standing. In other words, the college training must fill the vacuum which is produced by the unsatisfactory high schools. Recently, under the shocking impact of international political developments, statements and reports have been made public that condemn the condition of our high schools.

Let us not fool ourselves by thinking wishfully that the excellent reports of the numerous committees which study this situation will improve our high schools. The Flexner report had its impact on the sorry condition of our medical schools only because the Rockefeller Foundation and comparable foundations were willing to implement Flexner's proposals with staggering donations to private medical schools. The ensuing tremendous improvement of the majority of the private medical colleges then obliged the state medical schools to follow.

Since the number of private high schools is insignificant and public high schools cannot be changed by donations from private foundations, there is little hope that in the near future our high schools will change for the better. For a long time the vacuum represented by the high school will remain a heavy drag on medical education and will, mainly for economic reasons, prevent any extension of the medical school curriculum. Therefore, the three to four years of college training will have to stay with us, and modifications of the teaching programs in the college years will not be able fundamentally to reduce the damaging influence of the high school period.

Careful analysis of these two potentially vulnerable spots seems to indicate that the brevity of the curriculum and the overemphasis on the experimental medical science are closely connected. Moreover, thanks to a remarkable equilibration, the combined influence of these two apparent disadvantages has actually been favorable.

Medical School Curriculum

The training in medicine, surgery, obstetrics, and other fields that the American student receives during the two last years of his medical school curriculum is mainly in the hands of young instructors and assistant professors whose medicine is of very recent vintage. Participation in the active teaching of the third-year and fourth-year classes by experienced clinically oriented members of the faculty is limited to a relatively small part of the schools. The majority of the interviews of freshman-interns reveals that in many of the medical schools the lion's share of the clinical bedside training had been entrusted to the young teachers.

The latter, influenced and indoctrinated by the chiefs of their department, are vividly interested in theoretical medical research and have a healthy contempt for empirical medicine which cannot as yet be investigated by experimental methods. This is eloquently described by one of our most erudite academic teachers in the following words: "The atmosphere is experimental, the mood inquiring, the goal is understanding. The oft repeated aphorisms of the great clinicians are supplanted by information quoted from a variety of scientific journals."

Although the material taught during these years is far remote from clinical medicine, due to the active student participation, it is, nevertheless, of paramount importance. This two-year course in experimental physiology applied to patients is unique in the world and teaches the student to integrate physiological knowledge into clinical medicine. Thanks to this excellent preparation, the American physician, for the rest of his life, will always try to apply physiological principles to the understanding of disease. This knowledge proves to be a solid foundation for the clinical training at the bedside which, however, must be provided after the graduation, during the internship and residency years.

Since the two-year course of applied physiology at the bedside is an all important preparation for the post-medical-school training of our graduates, the last two years of the actual curriculum should be kept inviolate and intact. The few medical schools which permit their fourth-year students to work as junior interns—actually as interns—in hospitals, make a grave error. The favorable results of our medical schools are only possible because our institutions do not even try anymore to reach for the impossible, that is, to provide, in a period of four years, training both in basic theoretical medical fields and in applied clinical medicine. In this way the lack of emphasis on Hippocratic training in medical school, which at first view might impress as a weakness, ultimately proves to be the strength of our medical education.

This is only possible because, with true American know-how, we have enlarged our four-year medical school curriculum to a seven-to-eight-year medical training program by adding a mandatory internship and a nearly mandatory two to three years of residency. During the latter three to four years, true clinical medicine must be taught to our excellently prepared graduates; in other words, during this period the large part of medical knowledge which is empirical in nature must be put in the foreground. Although every opportunity must be sought to continue the indoctrination of the members of the house staff with the importance of results of experimental medicine, the latter cannot be placed in the center of the post-medical-school house staff training.

Hospital Educational Program

It is deeply regrettable that the greater number of the voluntary hospitals to which the teaching of clinical medicine during the internships and residencies has been entrusted have not succeeded in offering an attractive and effective educational program. "To follow a hospital-attendant through the wards and see what he does in his daily routine . . . is not medical education," Ewing wrote in 1916, and no truer words were ever written.

The small fraction of the numerous hospitals recognized for intern training which are actually chosen by the young graduates can be found in the small booklet containing the results of the National Intern Matching Program, issued every year on March 1. These figures clearly illustrate how few voluntary hospitals offer adequate teaching programs.

Personally, I have great respect and admiration for our budding graduates who do not succumb to the enticement of large monthly stipends, royal intern quarters, and lavish promises which can be summarized as "cows with gilded horns." Many of our future interns have only modest means and are, at the same time, burdened by heavy financial and matrimonial obligations. Nevertheless, they clearly prefer the hospitals which offer primarily a well-integrated teaching program but an inadequate financial reward and shun the hospitals where they will be abused as scribblers of medical charts, although higher emoluments and valuable fringe benefits are offered.

Many of the voluntary hospitals have understood that this unfortunate state of affairs could only be improved by organizing a plan of education for the young physicians who serve as interns or residents. For this purpose, in many voluntary hospitals a director of medical education has been appointed who must provide more systematic teaching both by lectures and by better organized ward rounds.

It has been brought out at previous sessions of this congress that the success of these well-meant efforts has been practically nonexistent as far as the recruitment of interns is concerned. It seems to me that the following point should be kept in mind.

Pure clinicians, mainly interested in empirical medicine, are often poor teachers. In this connection it must be emphasized that the approach to the diagnostic problem of a patient is exactly the same as the approach to a research problem—irrespective of the difference in the tools which are used in the attack on the problems. Only clinician-scientists who have been accustomed to tackle the difficulties of research problems know how to attack systematically the clinical problems which must be solved to find a satisfactory answer to diagnostic and therapeutic questions. Whether knowledge obtained by experimental methods or empirical knowledge obtained by observation and experience is used, the methodology which must be employed to tackle the problem remains the same. Thus, the pure Hippocratic clinician without interest in scientific research is usually an inefficient teacher, even of empirical medicine.

It would seem that the appointment of a clinical scientist as a director of medical education could considerably improve the educational programs of the voluntary hospitals. However, at all times it must be remembered that education can never be better than the teacher. Therefore, the director of medical education should not be a coordinator alone. Only if the clinician-scientist who directs the medical education is willing to do most of the teaching himself will the hospitals profit from the appointment of such an incumbent. In addition, he must organize weekly medicosurgical rounds, x-ray conferences, grand rounds and clinical pathological conferences, and other combined sessions so that his educational influence does not remain isolated to medicine alone but also reaches surgery and other departments.

In this connection it may be mentioned that in the history of American medicine the dynamic influence of the clinician-scientists on the progress of medicine has often made itself felt. When, thanks to the report of Abraham Flexner, a new era for medical education started in the United States, the newly appointed chiefs of departments were, of necessity, physicians and surgeons who had already made their reputation in clinical medicine and who, at the same time, had made contributions to the science of medicine. These clinician-scientists in their role as chiefs of departments made American medicine famous over the world and completely reversed the current of students which at the time ran from America to Europe. It seems possible that clinician-scientists might also be able to spark the teaching of medicine in the voluntary hospitals and attract American graduates as house staff members.

In the hospitals of the medical schools the attending staff usually consists of clinicians who have for years actively contributed to research in the department of medicine before they entered the field of clinical medicine. Most of these men usually continue their work in their old fields of interest. In most hospitals of the medical schools these mature clinician-scientists are the guiding spirits in the education of the house staff members. The purely scientifically and experimentally oriented members of the medical school faculty act only in a secondary, supportive role. This arrangement guarantees highly satisfactory and educationally profitable house staff assignments. This subtle balance would be disturbed and clinical teaching would suffer if the nonclinically minded medical school faculty would have too much influence on the bedside teaching in the hospital.

Let it not be said that such a situation can be easily remedied by the addition of a few good clinicians to the staff of such a department of medicine. As long as the upper echelon of the department unanimously looks down on empirical medicine, the students will accept this opinion. Young men are cruel critics, and, thus, the students will not refrain from demonstrating their disdain for physicians who feel that experience still plays an important role in the application of medicine at the bedside. In this hostile atmosphere the experienced clinicians will feel themselves to be unwelcome outsiders, and this will play havoc with their efficiency as teachers.

However, in far the greater part—perhaps even in all—of the medical school hospitals the clinician-scientist shoulders the major part of the clinical teaching. Hence, the number of interns and residents who flock to the medical school hospitals is large.

Summary

Thanks to the training and interest in research of the teachers in the medical schools, our medical graduates are well prepared for the progressive development of medicine which is bound to occur during their active medical life. In addition, they have the potentiality to develop into excellent clinicians during the post-medical-school years of house staff training. In the medical school hospitals the house staff training is highly satisfactory as long as the staff members who are clinician-scientists remain leaders in the bedside education.

The voluntary hospitals will only play a role in post-medical-school training if they put one or more clinician-scientists at the head of their educational programs. It follows that not only for the teachers in the undergraduate medical schools but also for the physicians responsible for the post-medical-school graduate training—both in university hospitals and in voluntary institutions—active interest and participation in research are mandatory requirements.

The teachers who are charged with the training of young medical graduates must be clinician-scientists, i. e., they must have, apart from their scientific orientation, a healthful respect for that part of medicine which is empirical in nature and is based on experience.

Beth-El Hospital, Linden Boulevard and Rockaway Parkway.

The latter, influenced and indoctrinated by the chiefs of their department, are vividly interested in theoretical medical research and have a healthy contempt for empirical medicine which cannot as yet be investigated by experimental methods. In addition, they have the potentiality to develop into excellent clinicians during the post-medical-school years of house staff training. In the medical school hospitals the house staff training is highly satisfactory as long as the staff members who are clinician-scientists remain leaders in the bedside education.

The voluntary hospitals will only play a role in post-medical-school training if they put one or more clinician-scientists at the head of their educational programs. It follows that not only for the teachers in the undergraduate medical schools but also for the physicians responsible for the post-medical-school graduate training—both in university hospitals and in voluntary institutions—active interest and participation in research are mandatory requirements.

The teachers who are charged with the training of young medical graduates must be clinician-scientists, i. e., they must have, apart from their scientific orientation, a healthful respect for that part of medicine which is empirical in nature and is based on experience.

RESEARCH ORIENTATION AND THE PRACTITIONER OF MEDICINE

Warde B. Allan, M.D., Baltimore

The research orientation and the practitioner of medicine is a subject that defies easy analysis and ready solution. The impact of research on the practitioner is just as important as the impact of research on the patient. As a matter of fact, the end-result is much the same. The practitioner is expected to filter out the good from the bad and recognize the practical applications of the results of these studies. The research physician should be in a position to disseminate practical and useful information to the practicing physician. On the other hand, the practitioner of medicine is in a situation where he, too, may do investigative work. I always think of that classic example in this regard, namely, Sir James Mackenzie's contribution regarding "Extrasystoles." After many years in practice and observing many instances of this disorder, he gave a most lucid analysis of the clinical significance of this type of cardiac arrhythmia. In the United States the historic work of William Beaumont and his famous patient, Alexis St. Martin, demonstrates what can be done when a situation arises that lends itself to clear thinking and patient application.

Patients are critical of the passing of the family physician and even suggest that socialized medicine is the answer. That is disturbing. Yet these same patients feel that "health" is a birthright and they should have access to all the latest achievements in diagnosis and therapy. These patients place an additional burden on the physicians. Not only must they be the "family doctor" but they expect them to keep up with all the sensational information so vividly described in the lay press.

Relationship of Research and Practice

Perhaps this change has occurred because of the influence of the "ivory tower doctors" on medical teaching. Perhaps medical schools are making stereotyped individuals out of medical students and suppressing intellectual curiosity. No doubt this has happened and is happening, but the recent trend in medical training in many institutions is in the direction of stimulating intellectual curiosity. If this training is more widespread and more young physicians develop this attitude, "research" or observation of the onset, course, and result of any given disease process might be better understood and, by the same analogy, better treated. As a result, the patient will benefit. It should be reemphasized that teachers of medicine should inculcate an attitude of thoughtful curiosity in the minds of medical students. The problems of diagnostic examination as well as the special problems that arise under these circumstances should be carefully analyzed. Available information referrable to these problems should be thoughtfully studied. The systematic pursuit and accurate documentation of the problems will make students better clinical observers and more appreciative of the research projects that are being done in these fields. It will eventually bring the practitioner of medicine and the research physician closer together.

Sir James Mackenzie pointed out better than anyone the opportunity for research in medical practice when he wrote: "Consider for a moment who is the individual in medicine who has the opportunity of seeing all parts of medical science in its true perspective. It is the general practitioner (i. e., the practitioner of medicine). He sees the conditions that predispose to disease; he sees its inception and the course it pursues, passing from the signs for medical treatment to the time when it calls for surgical interference. He sees the after-effects of the operation after the surgeon has claimed it as a success. If he is stimulated to inquire into the symptoms of the disease, he is brought in contact with every special department, and has the opportunity for estimating them at their true value."

What was true in Mackenzie's time is still true in our time. The practitioner of medicine is the backbone of medicine today. Though the field of each practicing physician is, in a sense, restricted, the horizons of adventure and observation are without limit. The practicing physician has a magnificent opportunity and duty to observe patients in this fashion and even add to the fundamentals of our knowledge of disease.

This is truly "research" of just as much importance as that of the laboratory worker, where modern buildings and elaborate apparatus seem to count for so much. When a physician runs into a perplexing problem in medicine, he should endeavor to spend some time in "investigating" that problem. Some of this information may be fundamental and worthy of publication. Indeed, it should be in the literature to help others. This is "fundamental research."

Associate Professor of Medicine, Johns Hopkins University School of Medicine, and member, Council on Medical Education and Hospitals, American Medical Association.

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 9, 1959.

To carry this a bit further, such research should be a great boon to the practitioner of medicine when he is faced with a complicated problem in one of his patients. His experience and documentation of that experience in his own office files is far more helpful than the textbook. They will be disappointed because there are few, if any, textbook cases in medicine anymore. Each physician's records should, if carefully kept, be a source of tremendous information and most helpful in meeting that physician's current problems.

Most practitioners of medicine are keenly aware of the importance of thoughtfully conceived and properly directed research. By the same token, they are greatly bothered by the enormous expenditures for so-called research. There is some justification for this worry when one considers the figures for medical research before and after World War II and 10 years later. In 1940, 45 million dollars was spent on research. Three million dollars came from government, 37 million from industry and philanthrophy, and 5 million from endowment. In 1947, 88 million dollars was spent on medical research—28 million from the government and 60 million from other sources. In 1957, 330 million dollars was spent (over half of this went to universities and medical schools); 186 million dollars was provided by government funds, 90 million by industry, and 35 million by philanthropy. It is only fair to add that both these latter figures are larger according to more recent surveys. Mr. Francis Boyer, chairman of the board of Smith Kline & French Laboratories, stated in an editorial in *Science* in August, 1958, that "a productive medical research program requires not only a lot of money but considerable wisdom in its spending."

It has been voiced that there is not adequate screening of the research programs that obtain funds from government sources. This is not entirely true. Yet, there are loopholes that are recognized. This is set forth in the final report of the consultants quoted in "Advancement of Medical Research and Education Through the Department of Health, Education, and Welfare," published in June, 1958; two of the conclusions were that "the system of national advisory councils and study sections be retained and expanded as required" and that "base grants for research and training be distributed on the basis of professional judgments of the unique capacities and needs of each institution, and not made to finance specific projects or programs."

In spite of the increasing "watch-dog" attitude toward research funds, many practitioners of medicine feel that Charles Pinckney's adage of "millions for diagnosis and not a cent for treatment" might well be paraphrased to "millions for research and not a cent for service." The schism between the research physician and the practicing physician is a real one and must be approached with some sense of reality.

Much has been made of having more medical schools and more medical students. This is reflected in a statement made by Surgeon General Burney: "Unless construction funds become available on a much larger scale than has heretofore been contemplated, the output of physicians will not keep pace with population growth and the needs of the nation for research workers will not be met." When one thinks about this statement, it is apparent that Burney feels that the roles of the practitioner of medicine and the research physician are inseparable. What is good for one benefits the other. Research should always be regarded as one of the activities of a teaching hospital and, perhaps, some of the better-equipped nonteaching hospitals. Though research is so regarded, much of the fundamental work is done in the laboratories of the "pure sciences." Research should be an important part of any hospital in that the unique training along these lines develops critical judgment. Even a superficial exposure to research is important. No earth-shaking discoveries may be made, but that experience makes the practicing physician appreciative of the painstaking and slow, or even relaxed, effort of the research physician.

Only a few, and I may add very few, physicians are equipped intellectually to do research. Many physicians are taking part in research programs that are nothing more than proving or disproving something already known. This is probably important, but there have been few striking fundamental discoveries when one considers the over-all number of projects going at the present time. I would be the last one to suggest that all these projects be curtailed or drastically limited. After all, something fundamental may come from a project of the utmost simplicity.

Dissemination of Knowledge

The research worker should not scorn the practitioner of medicine because he is not laboratory oriented. All of us cannot be. The practicing physician, if he is conscientious, can be of the most tremendous aid to the research physician by applying of principles discovered in the laboratory. It is the duty of the research physician to recognize this fundamental fact. The research physician and the practicing physician must work together. The one complements the other. The results of investigation must be properly disseminated among the practicing physicians to be appropriately applied to the care of the patient for whom it was originally planned.

That raises an almost insurmountable obstacle. Should this be done at medical meetings? Should it be introduced by having the results appear in the medical literature? Or should this information be spread far and wide through the drug house contact man and advertisement?

The obvious difficulties of accomplishing this by medical meetings hardly merits comment. Granted, the number of medical meetings is increasing in an amazing fashion. The various specialties and subspecialties plus numerous general groups have annual meetings and regional meetings. This outlet for information would seem sufficient. However, the number of practicing physicians reached is surprisingly small, forming but a minimal segment of all physicians. The medium of meetings leaves something to be desired because the information cannot be studied with care. I am sure that all of us have heard the results of superb investigation at a meeting but are unable to recount this information with any degree of accuracy. Meetings do serve their purpose in a limited way but are not the complete answer.

It is unfortunate that there is such a profusion of medical journals. No one practicing physician could possibly read all the journals; that would be a full-time job, even a life-time job. It is unfortunate, also, that so many articles appear for other reasons than to convey worthwhile information to the medical profession at large.

It is obvious that the results of research should not be given over to lay people. Yet this is happening in an ever-increasing way. It is astonishing that so much has been left to the pharmaceutical houses. This information is placed before the profession by a phenomenal advertising program that appears in many, but not all, medical journals. It is often presented in a more striking and eye-catching way than the text of these journals. Remarkable claims are made that are frequently misleading and lead to the masking of disease processes that would not happen if the medical profession were more alert. A brief illustration is the type of "cure-all vitamins" that contain folic acid and vitamin B_{12}. These remarkable capsules may well obscure an otherwise readily recognized case of pernicious anemia. The drug house contact men are an earnest, hardworking, and well-intentioned group. We might well ask ourselves if this is the proper way for the practicing physician to learn about the results of research. Too often anything that is new with an intriguing name seems to be considered the latest thing, the final work of some intensive investigation, whereas it is frequently something that has not proved its worth but is dressed up in a new costume with a fancy name.

Beckman, in a recent article entitled "To Use the New Drug or Not to Use It—That Is the Question," stated, "If a new drug is derived from an old folk remedy, the chances are that it is worth paying attention." He also stated that "all drugs, even the very best and least noxious of them, are psychologically and physically potential toxic agents." He stresses that, as a result of research, new drugs have brought new responsibilities to the manufacturer and to the physician. The former should be sure to explore all possible reactions of a new drug. The latter should learn how, when, and when not to use these highly potent compounds.

Would it not be an excellent idea to have a screening service whereby all information on worthwhile research could be catalogued? Such a method would give an excellent cross section and birds-eye view of proved research data. It is pertinent that the Institute for Advancement of Medical Communication has taken on the task of clearing the jammed channels of medical communication. Heading the list of projects under development by the institute is a specific plan for speedy interchange of research findings among investigators. The primary aim is to develop and test improved methods of communication in three main channels: (1) among research investigators, (2) between investigators and practitioners of medicine, and (3) between teachers and students in medicine. Such methods should be explored. Waldo Chamberlin, professor of government at New York University, has felt that national efforts along these lines would be "wasteful, inefficient, and expensive." He champions such a service or agency within the framework of UNESCO. These steps are in the right direction.

By the same token, the practicing physician should not wait to be spoon-fed but should avail himself of the opportunity to review the collected information, which reminds me of something I read the other day. I can't quote it, but, to paraphrase it, it is stated that there is no great objection to making the diagnostic road smooth but there is strong objection to allowing the mind to coast along in neutral.

The optimum in the practice of medicine is reached, unquestionably, by the acquisition of the art in the practice of medicine plus a practical application of the results of research. It is the obligation and even the privilege of the practitioner of medicine to bring all the wonders and achievements of medical research to patients, for whom it was originally intended. If each of us would honestly apply these principles in our daily practice, the rewards of research would far exceed all the worldly wealth expended to make such research possible.

MAINTENANCE OF THE SYNERGISTIC RELATIONSHIP OF EDUCATION AND RESEARCH IN MEDICINE

James A. Shannon, M.D., Bethesda, Md.

The profitable interplay between research and instruction in the educational process is perhaps best emphasized by the defensible statement that a vigorous medical education program is no more possible in the absence of research than in the absence of instruction itself. This was recognized at the turn of the century by a small number of institutions which initiated medical education as we know it today. We have come a long way since that time but have not really experienced this interplay on a broad scale until quite recently.

Subsequent to World War II, the nature of the relationship has been well understood—but not so the problems of its maintenance. These are inadequately studied and only infrequently acknowledged. For "maintenance" is a practical term. Given the desirability, even the essentiality, of achieving conditions which permit the cumulative effectiveness of medical instruction and research to be greater than the sum of the two, how—in specific terms—can this be accomplished? Whose responsibility is it? Where should the money come from, and under what circumstances should it be made available? These are pressing public issues as medicine faces the twin challenges of growth in size and in complexity.

Areas of Concern

There are three areas in which the maintenance of the synergistic relationship of teaching and research is of primary concern. The medical institutions themselves must have the resources and the resourcefulness to combine in the measure they deem appropriate the elements that make up a modern environment for teaching and research. This implies breadth (in terms of the range of disciplines and specialties involved); balance (in terms of the relative emphasis on teaching and research); stability (in terms of the basic financing of the institution and its full-time faculty); and independence (in terms of the ability of the institution to set up and pursue its own objectives). As one appraises our medical institutions today in relationship to their capacity to meet the challenges of tomorrow, it is abundantly evident that the principal factor will be resources rather than resourcefulness.

A second area of concern in the matter of balance between teaching and research is in the substance of the undergraduate and graduate medical educational experience itself. Certainly such factors as the increasing demands placed on physicians for understanding of diverse fields of medical science and the increasing importance of medical school and related environments as a source of scientists and teachers, as well as physicians, highlight the need for weaving the basic sciences—the behavioral and the physical as well as the biological—more closely into the fabric of our teaching institutions.

A third area for concern in the question of medical teaching and research has to do with the experience and contributions of physicians, scientists, and teachers who have completed their formal training but for whom education and research are a never-ending process. It is of the utmost importance that the mechanisms for interchange and refreshment be strengthened and expanded to permit the individual to advance in his own and related fields, for medicine has changed dramatically in the past 20 years and certainly will continue to do so. Teaching must be of a nature that permits subsequent growth of both student and teacher.

Although there are some who dissent, one feels a strong consensus that the present "balance," if you will, among teaching, research, and service in the United States represents the public and professional interest and is reasonable. Assuming this to be true, the problem is to maintain such balance in the years ahead. This problem can best be examined in the context of the medical school, where teaching, research, and service are inseparable.

I feel that the medical schools are at another critical stage in their general evolution. There is pressure to provide more physician training and at the same time to modify the substance of medical education. There is also pressure to expand the research base of the institution. These pressures become critical in the face of inadequate funds for operations and for plant expansion. Expressed in specific terms, this means an inability (1) to establish a suitable number of rewarding career positions; (2) to modernize, expand, or replace inadequate facilities; and (3) to develop institutional goals that are both reasonable and attainable.

Viewed in the more limited context of teaching and research, it is quite apparent that today the research function is well supported and is on a relatively firm base in both quantitative and qualitative terms. Funds are available from a wide variety of sources to finance research projects, research training, and research facilities. The federal government is the primary source of such support. But nonfederal sources, too, tend to give support more freely to research than to teaching or the general operations of the school.

Certainly such factors as the increasing demands placed on physicians for understanding of diverse fields of medical science and the increasing importance of medical school and related environments as a source of scientists and teachers, as well as physicians, highlight the need for weaving the basic sciences—the behavioral and the physical as well as the biological—more closely into the fabric of our teaching institutions.

A third area for concern in the question of medical teaching and research has to do with the experience and contributions of physicians, scientists, and teachers who have completed their formal training but for whom education and research are a never-ending process. It is of the utmost importance that the mechanisms for interchange and refreshment be strengthened and expanded to permit the individual to advance in his own and related fields, for medicine has changed dramatically in the past 20 years and certainly will continue to do so. Teaching must be of a nature that permits subsequent growth of both student and teacher.

Although there are some who dissent, one feels a strong consensus that the present "balance," if you will, among teaching, research, and service in the United States represents the public and professional interest and is reasonable. Assuming this to be true, the problem is to maintain such balance in the years ahead. This problem can best be examined in the context of the medical school, where teaching, research, and service are inseparable.

I feel that the medical schools are at another critical stage in their general evolution. There is pressure to provide more physician training and at the same time to modify the substance of medical education. There is also pressure to expand the research base of the institution. These pressures become critical in the face of inadequate funds for operations and for plant expansion. Expressed in specific terms, this means an inability (1) to establish a suitable number of rewarding career positions; (2) to modernize, expand, or replace inadequate facilities; and (3) to develop institutional goals that are both reasonable and attainable.

Viewed in the more limited context of teaching and research, it is quite apparent that today the research function is well supported and is on a relatively firm base in both quantitative and qualitative terms. Funds are available from a wide variety of sources to finance research projects, research training, and research facilities. The federal government is the primary source of such support. But nonfederal sources, too, tend to give support more freely to research than to teaching or the general operations of the school.

Director, National Institutes of Health, and Assistant Surgeon General, U. S. Public Health Service.

Read before the 55th Annual Congress on Medical Education and Licensure, Chicago, Feb. 9, 1959.

Since it seems likely that funds in support of medical research will continue to increase, and since it is not clear from where the needed funds for the teaching process will be derived, those who design and administer the research support programs have a special responsibility to take into account and strengthen the capacities of the schools to carry out their total mission.

The program of the U. S. Public Health Service is a case in point. Through its appropriations from Congress, a diverse pattern of support for research has come into being. In the aggregate, the programs this year provide more than 125 million dollars to the medical schools alone, including nearly 73 million for research projects, 35 million for training, and 17 million for research construction. In some schools, these grants and awards constitute as much as one-third of the yearly expenditures. Under these circumstances, the terms and conditions of Public Health Service support become matters of deep concern to the schools and to all those who are interested in their capacity, stability, quality, and independence.

The Twenty-School Study

As part of its continuing appraisal of the impact of its programs on the schools and related institutions, the Public Health Service has recently initiated—with the cooperation of the Association of American Medical Schools and the American Medical Association—an intensive, short-term study of 20 representative medical schools. The study is not yet complete, but certain trends and views are of interest even in preliminary form. They are stated here as a series of impressions gained by our staff as they have visited the schools and begun to analyze the data the schools have provided.

First, although the principle is axiomatic, there seems to be increasing awareness that good teachers at all levels need an opportunity to do research, and vice versa, and that it is part of a school's responsibility to make provision for its faculty to do both.

Second, although several years ago the number of medical schools with the funds and facilities necessary to permit faculty to engage in substantial research was small, that picture has changed. At present—whether one uses dollars, number of faculty members, or apportionment of faculty time as his measure—essentially all of the medical schools being studied are moving toward a 50-50 division between teaching and research. In some schools, the dollars and time spent on research actually exceed those expended for teaching.

Third, in general, the relative emphasis on research appears to be greater in private than it is in state institutions, but there are notable exceptions to this. Certain of the schools have indicated an increase from 10 to 50% in their research components during the past decade.

Fourth, as part of our study, the schools were asked to project their distribution of research and teaching effort for the next 10 years under two assumptions: (1) with federal funds held constant and (2) with federal funds increasing at whatever the individual school felt to be an ideal rate. Under both assumptions, schools which now have a relatively low research expenditure propose to increase it. Given a free hand, private schools project a greater emphasis on research than state schools.

From these sketchy observations, it would appear that research in medical schools is becoming more and more a primary function. It will undoubtedly be necessary for the schools to recognize the inevitability of permitting teachers to expand their research function. One would wish that the granting agencies could be equally broad minded about permitting research-supported people to engage in or expand the teaching function. I am reminded, for example, of the fact that our own research fellowships carry a limit of 10% on the amount of time that can be devoted to teaching.

Our study (since our primary mission at the National Institutes of Health is the conduct and support of medical research and the development of resources through research training and research construction programs) is focused on the impact of our present programs and on the ways they should be changed in character and may change in dimension in order to meet the needs of medical science and of society in the years ahead. Naturally, most of the facts and opinions we seek have to do with the research side.

Support of the Teaching Function

It will come as no surprise to you, however, as it was not to us, that the schools studied put funds for construction of teaching facilities as their first priority need and funds for general operating expenses second.

In this, it seems to me, lies the primary challenge to the maintenance of synergism between the research and teaching functions in medicine. Established and accepted sources, both public and private, today support the research function adequately. The educational function, on the other hand, is restricted from its needed growth, both qualitatively and quantitatively, because adequate funds are not available.

This is a painfully familiar theme to those of you who have long been concerned with our medical institutions and have evidenced that concern in your personal and professional lives. It is a problem that will certainly be solved, but slowly and on the basis of small individual steps and public and professional awareness leading ultimately to consensus and united action.

In the meantime, given only the existing patterns of support, some things can be done to help avoid placing even greater stresses on our medical schools and related institutions. They all stem from understanding of the basic interdependence of the functions of the schools, requiring the terms and conditions of support to be designed with an awareness that *no one* function can reach its optimum level unless the other functions are maintained to permit a balanced and unified total effort.

For the different sources of support—private or public and federal, state, or local—this responsibility to support a part in the context of the whole will be evidenced in varying ways. For the National Institutes of Health, for example, it takes the form of continuous program modification, within our statutory authorities, so that needs that become evident to us are met to the best of our ability. In this, it must be remembered that NIH, as the principal medical research arm of the federal government, must be responsible to the people and to the Congress, must operate within policies set by the executive branch, and, at the same time, must be responsive to the needs of scientists and their institutions.

At any given point in time, elements of our program are in the process of modification, since they seek to be responsive to changing needs. Today, for example, we are seeking, through our legislative and appropriation processes, to modify our programs to achieve four primary objectives: (1) the ability to pay the full costs of the research supported by our grants, instead of only part of such costs as now provided under our 15% limitation on the payment of indirect costs: (2) the authority to provide for strengthening and stabilizing the research base by making available to the medical schools and related institutions what we now call institutional research grants (such fluid funds for research purposes, supplementing but not competing with research project grant funds, would permit the schools to regain a measure of discretion and control over their own research activities); (3) measures which will permit the schools to increase the number of full-time positions in research with faculty tenure; and (4) a gradual change in the specificity and duration of research project grants, so that they are awarded for less rigidly defined studies and accorded support over longer periods of time.

All of these are derived from our perception of the needs of the schools, the long-range as well as the immediate strength and productivity of their medical research effort, and the established role of the federal government as having direct interest in the medical research component of the nation's institutions of higher learning.

I cannot surmise what the fate of these concepts may be. But I thought I should share our thoughts with you who are vitally concerned with the many factors influencing future developments in medical research and medical education, recognizing—as I know you do—that these and all other major modifications in our programs must be measured in a wide variety of professional and public forms before they can be brought into being.

Such program developments, whether they deal with the substance of science or a mechanism for its support, suggest that our attention is now centered primarily on the needs of the institutions which are the heart of our nation's research and teaching effort.

Superseding all other needs, in the long run, is the need of the schools to achieve, and to speak with, a strong and unified voice. The hopes and expectations of millions of Americans and of people everywhere are centered in the medical institutions, and the groups with a special interest in the schools are willing, even eager, to speak in their behalf. It is right that they should do so. But the profession must not depend solely on such support. A way must be found for the schools themselves to capitalize on the latent power and prestige that is implicit in their position of leadership in medical affairs.

POSTOPERATIVE PANCREATITIS.—Acute pancreatitis is found occasionally as a postoperative complication, mostly after biliary tract surgery and after gastrectomies. This is a serious, often fatal, complication. . . . Since a fatal outcome may possibly be prevented by therapeutic measures directed against the pancreatitis, it is of utmost importance to make the diagnosis in time, and the only means of doing this is the serum amylase test. If the serum amylase level is elevated following operation, we may well assume that we are dealing with a pancreatic complication. One of us has made it a routine to order serum amylase tests during the first postoperative days if the pancreas was traumatized at operation and likewise after all upper abdominal operations if the postoperative course is not as smooth as anticipated. We had a number of cases with postoperative rise in serum amylase. All of them recovered uneventfully after being placed on a pancreas-protective regimen, which, in addition to routine orders, consisted of repeated intravenous administration of 6% Dextran solution, one of the best means to combat pancreatitis.—H. L. Popper, M.D., and H. Necheles, M.D., Ph.D., Pancreas Function Tests, *The Medical Clinics of North America*, March, 1959.

MAJOR FACTORS INVOLVED IN RECONSTRUCTING THE MEDICAL CURRICULUM

John A. D. Cooper, M.D., Ph.D., Chicago

The ferment and rapid changes characterizing the status of medical education in the past decade give every promise that future developments will cut deeply into the fabric of our present patterns for the preparation of the physician. There are probably a number of as yet unforeseen factors which will effect further alterations in our present concepts of the curriculum. Out of the many possible ones, I have chosen three topics to bring into focus in my discussion. They fall in the general areas of the student, a liberal education for medicine, and the changing social character of our population.

The Student

I would first like to turn attention to the students who will enter our medical schools of the future. A basic and integral part of any educational program, their qualities and abilities help mold to a considerable extent the nature of the program.

Despite their importance in the scheme of things, far too little attention has been paid to improving the quality and size of the pool of applicants from which choices can be made in selecting our classes. Projective reports of increasing numbers of applicants to medical schools in the next decade do not give information about their quality. There is good objective evidence that the quality of the applicants and in turn of those accepted is declining. As recently as 1950, 40% of enrolled medical students had premedical grade point averages of A, an equal number had a B average, and about 20% entered with a C average. For the 1955-1956 class, only 16% had an A average, 71% had B averages, and the remainder had C averages. There has been little change in the 1956-1957 medical class.[1] The figures I have given represent averages, and there is considerable variation among the individual medical schools. Some are blessed with student bodies in which 70% have A averages in their premedical preparation, but some are not so richly endowed and 70% of their students have C averages.[2] Although grades do not entirely establish suitability for the study of medicine or subsequent practice as a physician, they certainly serve as one of the guideposts.

This turn of events, unless it can be reversed, will create a real dilemma—the increasing mass of scientific knowledge in medicine, the medical sciences, and the behavioral sciences and the deepening complexity of medical practice call out for students with even greater intellectual capacity and dedication than in the past. If students are not equal to this heavier burden, there can only be compromise with the high level of education necessary to properly prepare them for the profession.

The changing social character of the student is probably responsible in part for the change in the attractiveness which medicine holds for him. Modern youth seems less given to dedicated pursuits and the desire for achievement. Idealism is on the wane, and the individual has difficulty in establishing and maintaining values and goals which differ from those of the masses. Conformity and homogeneity characterize the age, and there is every promise that the trend will not be interrupted in the future. These attributes do not mark those who are interested in and willing to undertake the long and difficult preparation for medicine and to accept the demands which practice requires.

Medicine is finding increased competition for the pool of top-ranking students because it no longer occupies the unique position as a profession which it held in the past and shared largely only with law and the ministry. The professions open to the college graduate are now much broader, and they provide the prestige, intellectual satisfactions, and financial rewards comparable to those offered by medicine. Furthermore, faculty members in the college are in an ideal position to pick out the best students in their classes and convince them to abandon their original intent to study medicine and elect instead graduate study in the department. The letters of recommendation which come to admissions committees with the statements "He is too good a student for medicine," or "I have tried to convince him to follow a career of research in chemistry," tell the story of the cases where they have failed. Medicine has no opportunity to effectively combat this spiriting away of our best students.

The vast sums of money available for fellowships and research assistantships in the expanding research budgets almost guarantee the total expenses of graduate education for all but a small fraction of students in the physical, biological, and behavioral sciences. Medicine has no equivalent source of subsidy for its students. In addition much research, even in areas traditionally reserved for medicine, is being carried out by investigative teams which include both physician and nonphysician scientists. The members of the group participate essentially as coequals, and the physician oftentimes does not rank above his colleagues, even though the problem being studied is directly concerned with a disease process. This new freedom of opportunity permits talented young men and women to partici-

Read before the Annual Congress on Medical Education and Licensure, Chicago, Feb. 10, 1959.

pate in challenging and rewarding activities in fields closely related to medicine without the requirement for an M.D. degree. The physician retains his unique status only in being responsible for the patient's welfare, a privilege which apparently has diminishing appeal for the high-ranking modern student. As the scientific and technological bases of our existence further broaden, we can anticipate only increased competition by engineering schools and graduate programs outside of medicine for the relatively ever less adequate pool of good students.

The inordinate length and cost of the total educational program for medicine, measured not only in the monetary outlay but also in the years of income which it denies, is certainly having its influence on career choices. The biochemist in a graduate program can begin to support himself and a family even before he receives his Ph.D. degree. Engineers have little difficulty in finding good jobs after graduation. Because of the student's long period of study in medicine during the years when his contemporaries in other fields are starting their families, and his prospect of additional semi-indentured service as an intern and resident, medicine is finding increased difficulty in competing with the attractions of other professions. The declining fraction of college students seeking a career in medicine and the well-established increased future needs for physicians compound even further the predicament in which medicine may find itself.

There are partial solutions to these problems already apparent: an active recruitment program in the high schools and colleges similar to the one so successfully employed by engineers, well-considered plans for shortening of the over-all program, and the granting of higher professional and economic status to the physician in specialty training.

If we fail to attract into medicine an adequate number of top-notch students who can acquire and use the broader and deeper understanding of basic biology and behavioral sciences in the care of patients, our educational program will of necessity have to lower its goals to fit the students with which it is provided.

Liberal Education in Medicine

The rapidly mounting mass of knowledge basic to medicine and the medical sciences is posing serious difficulties in properly relating it to patient care and the present patterns of medical education. There is every likelihood that the difficulties will increase, because knowledge is increasing not linearly but exponentially.

Hope for success in meeting this challenge requires that bold action be taken to reappraise our present concepts for preparing the physician. Although we are quick to denounce premedical education directed toward the accumulation of facts rather than the deliberate cultivation of the power to think and to think painstakingly, we are loath to apply the same criteria in evaluating our own educational programs. We ask that the colleges not give us computers which regurgitate without modification or understanding the facts which have been programmed into them, but all too often the educational program for medicine lays stress on these accomplishments.

Experimentation is clearly called for, and its beginnings are already visible. As Darley pointed out in this Congress, the methods of patient care and medical education must be subjected to the same study and experimentation accorded to the scientific disciplines. The experiments now in progress are providing valuable information, but their scope is still inadequate. As they spread there will be an effect on the medical curriculum through the diversity which they foster.

One of the probable directions in experimentation will be the introduction of greatly increased flexibility into the present, still overrigid curriculum. The flexibility will appear in the total length of the educational span for medicine. Students will be permitted to progress at the rate which their emotional development and scholastic achievements dictate. This philosophy, which has pervaded the thinking at the secondary school and college level, has made little inroad into medical educational circles.

Increased flexibility will permit design of programs to fit the interests and requirements of the individual student. Every graduate of the medical school will not have had the same lock-step curriculum as his classmate. Acceptance by medical educators and licensure bodies of the thesis that the sum total of medical knowledge cannot be imparted to the undergraduate medical student and that students come with individually varying needs and resources will open up the possibilities of constructing a program of "liberal education" for medicine. There is little doubt that there will be far-reaching effects on the medical curriculum.

Changing Social Character of Our Population

The third factor which I wish to consider that will probably have an effect on medical education is the changing social character of the American people. This effect will occur indirectly through its influence on medical practice and the concept of the physician's responsibility for the emotional problems of his patients.

The rediscovery of the patient and the concept of comprehensive medicine describe important directions being taken in modern medical care. The importance of orienting medical students to look beyond the pathological process and treat the patient as a whole is receiving wider acceptance. Opportunities for the unhurried recognition of factors within the patient and his ecology which might be involved in the aggravation or cause of his illness, or in the promotion of his health, are beginning to be supplied in the clinical teaching programs of an increasing number of medical schools. One important facet of the "whole patient," however, has not received the attention it is due—the way in which he is changing in our developing culture. This information is becoming of increasing importance because of its influence on our concepts of the role which the physician can be reasonably expected to play in coping with the character disorders which he finds in his patients.

The marked alterations taking place in the social character of our time have been widely chronicled by Riesman and associates,[3] Commager,[4] Wheelis,[5] and others. The influence which these changes have exerted on the practice of psychoanalysis has been pointed out by Wheelis in his book entitled "The Quest for Identity." I would like to broaden the ideas which he develops to wider areas of medical practice.

We are living in an age of uncertainty. As Wheelis has written, "The questions of adolescence—'Who am I?' 'Where am I going?' 'What is the meaning of life?' receive no final answers. Nor can they be laid aside. The uncertainty persists. The period of being uncommitted is longer, the choices which terminate it more tentative."

The neurotic pattern and personality problems are evolving from the symptom neurosis so clearly described by Freud to character disorders whose amelioration requires provision for the patient of a value system, answers to the "confusions of the age," and direction in deciding what is worth fighting for and how strong the fight should be. The enormity and nature of the help required by the patient in orienting his life raise serious questions about the part which the physician should take in helping with their solution. The attention and support which the patient must have in solving the problem of his identity are of a different order of magnitude than those required for freeing man from the internal tyranny of his character. The approaches and techniques developed to cope with yesterday's problems do not meet the needs of a completely different type character disorder.

The enormity of the challenge presented by the uncertainty which pervades our culture will make it necessary to develop new techniques. Unless there is a marked increase in the relative number of physicians to the population, there will not be sufficient time in the physician's day to deal with more than the psychological parameters most closely related to the presenting disease. Complete rehabilitation of the patient will require the interplay of a team of which the physician is only one member. The medical schools must foster the development in their students of the attitudes and knowledge which will permit them to take the fullest possible advantage of the help which this combined approach can offer. Psychiatry and psychology as they are presently conceived are not designed to provide individuals with values and goals—it would appear that the sociologist may supply the direction which the problem requires.

These represent three factors which I think may have considerable influence on our education for medicine in the future—there are many others that I might have chosen but time and clouding of the crystal ball suggest that I end here.

POSTOPERATIVE STRICTURES OF THE BILE DUCTS.—Man-made strictures of the bile duct . . . account for 80% of all the so-called benign or simple strictures of the bile ducts. . . . Postoperative stricture of the bile duct is one of the most tragic complications seen today in the practice of abdominal surgery. . . . The tragedy of this calamity can be gauged by remembering that 70% of the patients are women, 40% are under the age of 50, and only about 60% of these cases are permanently cured by a reconstructive procedure. It is estimated that some 30% of such patients will eventually die from the attempts made to repair the stricture or from the effects of intermittent or complete biliary obstruction. Many of these unfortunate patients have had several unsuccessful operations for relief of the obstruction before being referred to a specialist in this field. . . . It is impossible to estimate the incidence of postoperative stricture of the bile passages, but there is no doubt that injuries of the common duct related to cholecystectomy have increased, and it cannot be questioned that the number of common duct injuries is much too great.—R. Maingot, Post-Operative Strictures of the Bile Ducts, *Annals of the Royal College of Surgeons of England,* March, 1959.

CLINICAL NOTES

COMPRESSION FRACTURES OF THE THORACIC VERTEBRAE IN A PATIENT WITH TETANUS

Cornelius Colangelo, M.D., Chicago

Tetanus is a disease caused by an anaerobic bacillus, Clostridium tetani, and characterized by stiffness of the jaw and tetanic spasms of the neck and back. The agent causing tetanus is found in soil and in the gastrointestinal tract of man and many animals. It has been isolated occasionally in man from the body surface and oral cavity. Essential to the development of tetanus is the preexistence or fresh deposit of spores in tissues favoring their growth, i. e., traumatized, inflamed, or necrotic tissue. On occasion such conditions prevail without trauma, and in these tetanus may develop without any apparent wound. The case to be presented is in this category.

The tetanus bacillus elaborates a toxin affecting the anterior horn cells of the brain stem and cord and the myoneural end-plates. Thus, the chief clinical manifestation is tonic spasticity of various voluntary muscle groups, and the symptoms vary with the muscles involved. On this tonic spasticity (rigidity) are imposed intermittent tonic spasms (tetanic convulsions).

The onset is usually marked by restlessness, generalized aching, irritability, difficult swallowing, and fever of 100 to 104 F (38 to 40 C). Stiffness of the jaw is the most common initial symptom and is due to masseter muscle spasm. As the disease progresses, rigidity of the neck, back, abdomen, and extremities becomes more pronounced, and there may be a grotesque grin due to involvement of the facial muscles. The masseter muscle spasm becomes severe and restricts mouth opening (trismus).

Tonic spasms are frequent, brief, painful, and accompanied by sweating. The teeth are clenched, the back and neck are arched (opisthotonos), the abdomen is taut, the extremities are rigidly extended, and the patient cannot cough or speak due to contraction of the muscles of respiration. If the spasm lasts long enough, interference with these muscles (diaphragm and intercostal and glottic muscles) can produce anoxia, cyanosis, and even death. The cause of death, however, is usually less apparent and is generally attributed to exhaustion.

The symptomatology is quite varied, especially at the onset when there may be headache, chilliness, stiffness of gait, abdominal pain due to muscle spasm, pain in the back and neck, and tongue biting. In those patients who recover, the signs and symptoms reach maximal intensity and then gradually recede.

According to the "Textbook of Medicine," edited by Cecil, Loeb, and others,[1] there are no laboratory procedures which are helpful in the specific diagnosis or management of tetanus. It further states that bacteriological examination as a means of diagnosis not only is almost worthless but also may be dangerously misleading.

Treatment in tetanus is based on sedation to control the irritability of the nervous system responsible for muscular rigidity and spasms and on destruction of the toxin or of the bacillus elaborating it. Of almost equal importance is the use of antibiotics to control the frequent complication of pulmonary infection.

A common complication of tetanus in children is compression fracture of several thoracic vertebrae. Caffey[2] states that Dietrich, Karshner, and Stewart found compression fractures of the thoracic vertebrae in 70% of a group of children who had recovered from tetanus. One or more segments near the apex of the thoracic curve were affected. Veronesi[3] found "vertebral changes" in 87% of a group of tetanus patients who were 1 to 20 years old. He described flattening, sometimes considerable, of the thoracic vertebrae, especially T-4 through T-7. The superior portion of the body was usually involved. This article was based on work done in Brazil where tetanus is common and was published in 1956. From then to September, 1958, the medical literature provided only two references to vertebral fracture,[4] and these were from Russia where tetanus is also probably common. Each reference concerned fractures of the thoracic vertebrae in a child.

Report of a Case

The case of tetanus to be reported was considered noteworthy because multiple compression fractures of the thoracic region of the spine developed in the course of the disease and because the disease occurred without a visible wound or trauma.

The illness began in this 16-year-old boy with chilliness, diffuse backache, stiffness in rising out of chairs, and lassitude. The next day the jaw was stiff, markedly limiting opening of the mouth, backache was severe enough to prevent sitting erect, thirst was prominent, and swallowing was so painful that only fluids were taken. The patient described

---

From the Alexian Brothers Hospital.

this symptom as a "very sore throat." That night there was fever of 103 F (39.4 C), restlessness, and groaning due to generalized aching. During the next two days there was chilliness, fever, poor appetite, epigastric soreness, inability to walk straight, painful stiff neck, and backache so severe that a pillow had to be placed behind the back to permit sitting. At this time he was seen by a physician who promptly sent him to the hospital.

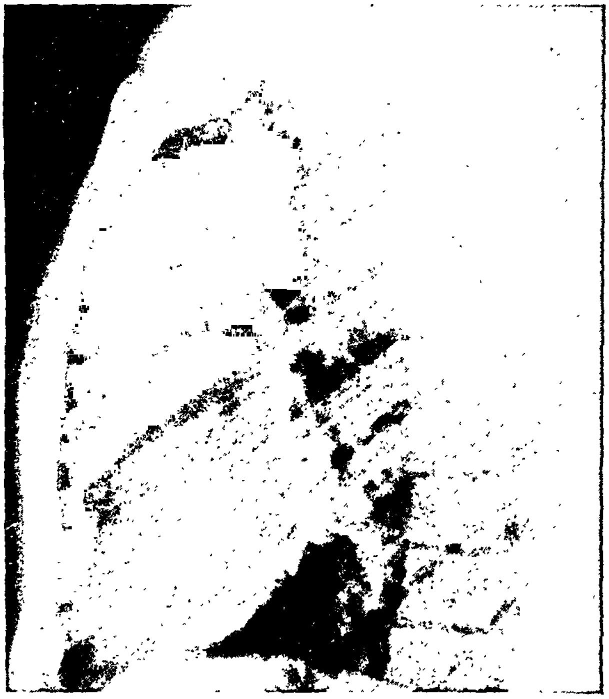

Fig. 1.—Normal lateral thoracic part of spine.

Examination of the boy on his admission to the hospital revealed the temperature to be 98.6 F (37 C), pulse 98, respirations 18 per minute, and blood pressure 130/60 mm. Hg. There was pharyngitis and gingivitis. The tongue was inflamed and showed several shallow ulcers. The jaw was stiff, greatly restricting opening of the mouth. The muscles of the neck, face, and back were stiff, and coughing or turning caused pain in the back. The abdomen was rigid, and there was left hypochondriac tenderness. There were crepitant basal rales bilaterally. There was no history of a previous significant illness, no history or evidence of a wound or contusion, and no history of immunization against tetanus.

Because of the basal chest rales, posteroanterior and left lateral chest films were made, as is routine in this hospital. There was haziness in the right costophrenic sinus area consistent with pleuritis or atypical pneumonitis. On the left lateral view the thoracic vertebrae appeared normal (fig. 1).

During the next two weeks, the patient had a temperature of 100 and 101.4 F (37.8 and 38.5 C) on the first two days, but thereafter fever was insignificant. Prominent features were frequent, daily, brief, painful tetanic spasms of the neck and back; opisthotonos; trismus; frequent troublesome cough with yellowish expectoration; painful swallowing restricting food intake to fluids and occasionally preventing even that; fetor oris with gingivitis; and ulcerative glossitis. There was also poor appetite, pain in the chest and abdomen, and occasional tongue biting.

There were three episodes of dyspnea and cyanosis associated with efforts to cough and expectorate. The first lasted 10 minutes and produced brief syncope; the other two were shorter. All were relieved by placing the patient upright. During these attacks the patient felt that he was strangling or choking, and he could not cough or speak.

Aching in the thoracic region of the spine became severe during the second week, leading to x-ray examination of the cervical and thoracic regions of the spine on the 19th day of the illness. The cervical region was normal. The thoracic region showed compression fractures in the bodies of T-3 through T-9 involving the superior portions. T-5 showed the greatest compression, amounting to 60%. There was equivocal anterior subluxation of T-3 and T-4. Thoracic kyphosis was slightly increased, the apex of its convexity being at T-4–T-5 (fig. 2). The patient then was fitted with a back brace.

The laboratory findings were not diagnostic. The entrance examinations showed 1+ albumin in the urine; leukocytes, 11,000 per cubic millimeter, with 5 eosinophils; negative serology; and a sedimentation rate of 34 mm. (normal 0-9). The cerebrospinal fluid was normal. No cells were seen in it, and a 48-hour culture was negative. A throat culture did not produce any specific growth. A gum swab on Gram staining revealed many mixed organisms. Culture showed a mixed growth resembling alpha streptococcus, Bacillus subtilis, nonpathological Neisseria, and Hemophilus hemolyticus. The following blood analyses were normal: calcium, phosphorus, urea nitrogen, acid and alkaline phosphatase, total protein, and albumin and globulin levels.

Hospital treatment included administration of analgesics and aspirin, as needed for pain; cough medicine, as needed; sterile penicillin-dihydrostreptomycin for suspension (Combiotic), one vial daily for the first three weeks; chlorpromazine (Thorazine) hydrochloride, 100 mg. daily intramuscularly for the first two weeks, 150 mg. for the third week, 200 mg. orally daily for the next three weeks, 100 mg. daily for one week, and then discontinued; methocarbamol (Robaxin), 5 mg. four times daily, until improvement began, then decreased gradually and discontinued at the end of the seventh hospital week; phenobarbital, 2 grains (0.12 Gm.) daily for the first week, then 4 grains (0.25 Gm.) daily until discontinued at the end of the eighth week; diphenhydramine (Benadryl) hydrochloride, 50 mg. twice daily from the third week through the remainder of the hospital stay; diphenyl-

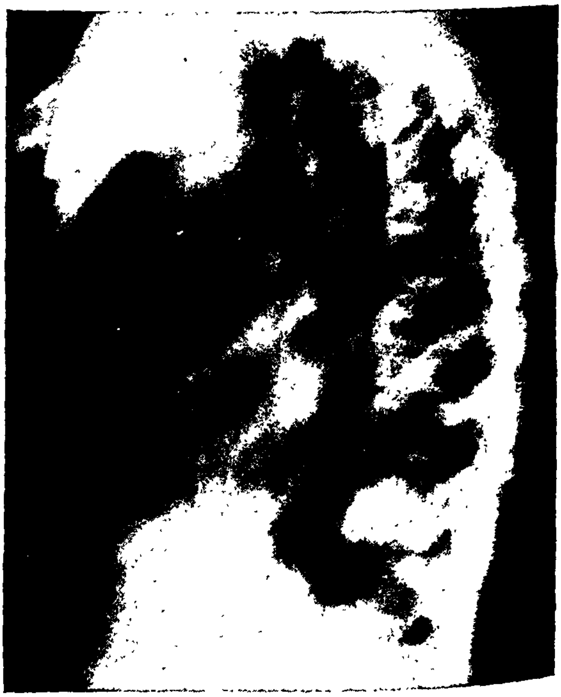

Fig. 2.—Lateral film of thoracic part of spine showing compression fractures in bodies of T-3 through T-9.

hydantoin (Dilantin) sodium, 1.5 grains (0.1 Gm.) twice daily for the two and one-half weeks in the later part of hospital stay and then reduced to 1.5 grains daily for the remainder of the hospitalization; and 50,000 units of tetanus antitoxin during the early part of the illness, followed by three doses of 5,000 units at spaced intervals.

The symptoms reached their peak coincident with the discovery of the spinal fractures. Thereafter they began to recede slowly and intermittently, although opisthotonos and infrequent tetanic spasms were still present at the end of the fourth week. At the end of the seventh week there were no symptoms or findings of tetanus. Repeat films of the thoracic region of the spine at this time did not show any change from the first films other than the development of osteoporosis due to inactivity.

The patient was discharged on the 61st day of the illness, wearing a back brace and walking.

Comment

Fractures of the thoracic region of the spine are a frequent complication in childhood tetanus. The physiological kyphosis of the thoracic part of the spine in the juvenile, the sustained muscular contraction, plus the tetanic spasms combine to produce fractures of these spongy, relatively delicate cubes of bone. The apex of the thoracic kyphosis acts as the fulcrum.

The source of the infection in this patient is not known. It could have arisen in the severely inflamed gums and tongue. The case report illustrates the value of the lateral view in the routine roentgenologic examination of the chest. It is admitted that this is a rare instance, yet without the normal appearance of the thoracic area of the spine on the earlier lateral chest film the later films of the spine might have been more difficult to evaluate.

Summary

A case of tetanus occurred in a 16-year-old boy. The source of the infection was not apparent, and the infection was complicated by compression fractures of the third through the ninth thoracic vertebrae. The patient recovered.

1200 Belden Ave. (14).

COUNCIL ON FOODS AND NUTRITION

Report to the Council

The Council has authorized publication of the following report. The Council is pleased to acknowledge cosponsorship of the report by The Nutrition Foundation, Inc.

Philip L. White, Sc.D., *Secretary.*

AN ADEQUATE DIET

Leonard A. Maynard, Ph.D., Ithaca, N. Y.

An adequate diet is one which meets in full all the nutritional needs of the person. These needs are set forth for infants, children, boys, girls, men, and women in the report[1] entitled Recommended Dietary Allowances. The data in this report are based on an exhaustive review of all of the research and other information available up to the time of its publication in 1958. These data are considered to provide the basis for a fully adequate diet for all normal persons as is indicated by the following quotation:

> These allowances are designed to maintain good nutrition in healthy persons in the United States under current conditions of living and to cover nearly all variations of requirements for nutrients in the population at large. They are meant to afford a margin of sufficiency above minimal requirements and are, therefore, planned to provide a buffer against the added needs of various stresses and to make possible other potential improvements of growth and function.

In providing for the needs of all healthy persons, including those subject to various stresses, the recommended dietary allowances exceed the requirements of many persons. Thus, failure to meet them fully does not mean that a given person is thereby undernourished. On the other hand, the allowances are not designed to be adequate to meet additional requirements which may be associated with disease or needed by severely depleted persons and which may call for supplementation ac-

cordingly. The allowances should not be confused with the generally lower minimum daily requirements established for the Food and Drug Administration for labeling purposes and considered to be the amounts needed to prevent symptoms of deficiency and to provide a small factor of safety.

There are a few nutrients known to be essential in human nutrition or presumed to be essential, on the basis of animal experiments or in vitro studies, for which definite allowances have not been established. The Food and Nutrition Board report discusses these cases and cites the data available as to quantitative requirements and as to their content in foods. From these data it appears highly probable that any needs for these nutrients can be met readily by a mixed diet that is adequate in other respects. A case in point is represented by various trace elements which are associated with enzyme systems and are thus presumably essential in minute amounts but which are widely distributed in foods of either plant or animal origin.

Nutrient allowances are useful in practice only as they are translated into diets. Fortunately, the food supply of the United States is so large and provides such rich and varied sources of the nutrients needed that it is readily possible for everyone to have an adequate diet from foods available to him. The abundance of this food supply is indicated by the fact that during recent years, the per capita, retail, edible supplies of protein, iron, vitamin A, thiamine, riboflavin, niacin, and ascorbic acid have exceeded the per capita allowances for these nutrients by 40% or more. Thus, though surveys continue to show that a substantial number of households and individual persons fail to consume diets which fully meet the recommended dietary allowances for all nutrients, it is not to be construed necessarily that needed food supplies are unavailable or that the individual persons in question are malnourished. Such surveys do indicate a widespread lack of appreciation of the importance of an adequate diet and a lack of knowledge of how to select it.

Actually, due to the great variety of the food supplies readily available, there are many ways in which an adequate diet can be obtained. A very helpful guide for food selection has been issued[2] by the United States Department of Agriculture. In this publication, foods are divided into four groups, and directions are given as to how to choose a diet from these groups.

The milk group includes cheese and ice cream which may replace part of the milk. It is suggested that children receive three or four cups of milk, teenagers four or more cups, adults two or more cups, pregnant women four or more cups, and nursing mothers six or more cups daily. The milk group is counted upon to furnish the major portion of the calcium needs. It is an important contributor of high-quality protein and riboflavin and also provides many other vitamins and minerals, as well as carbohydrates and fat to meet energy needs. To supply needed vitamin D for infants, children, adolescents, and pregnant and lactating women, milk should be the product enriched in this nutrient.

The meat group includes beef, veal, pork, lamb, poultry, fish, and eggs, with dry beans, dry peas, and nuts as alternates. Two or more servings daily from this group are recommended. These foods are of special importance for the high-quality protein furnished. They are also important sources of iron, thiamine, riboflavin, and niacin and supply other minerals and vitamins as well. Variable amounts of fat, useful for energy needs, are furnished.

The vegetable-fruit group includes a long list of foods from which four or more servings daily should be selected. It is specified that these servings should include a dark green or deep yellow vegetable at least every other day to provide vitamin A, a citrus fruit or other fruit important for vitamin C daily, and other fruits and vegetables including potatoes. In addition to their large contributions of vitamins A and C, the four servings from this group also provide significant amounts of iron, niacin, thiamine, and certain other vitamins and minerals.

Four or more servings daily from the bread-cereals group are suggested. This group includes whole grain, enriched, or restored cereals. It is important for its contribution of thiamine, niacin, and iron and also furnishes worthwhile amounts of protein and certain other minerals and vitamins, depending on the specific source. The group provides these various nutrients and also calories at a relatively low cost.

The United States Department of Agriculture publication states that the minimum number of servings suggested forms the foundation for a good diet which can be rounded out by more of the same foods or others not mentioned, such as table fats, other cereal products, and sugar, to provide the additional calories and nutrients needed. The publication gives details as to the nutritional contributions of the foods in the different groups and as to how a daily food plan can be developed to insure an adequate diet. The information is summarized in a four-page pamphlet[3] which can be obtained in quantity from the Superintendent of Documents, U. S. Government Printing Office.

MEDICINE AT WORK

- *Meals on Wheels*
- *Discipline Committee*
- *Libraries and Aged*
- *Figuring Fees*
- *Medical Museums*

Needed: Smog Doctor

Los Angeles County is looking for an epidemiologist. The position will be under Civil Service and will pay $13,284 per year. The job—smog doctor.

Angeleños have spent years reading, through smog-irritated eyes, almost daily news stories of governmental efforts to abate the city's air pollution problem. Industrial smoke ordinances, bans against trash fires, plans for auto exhaust attachments, and dreams of importing fresher air through mountain tunnels have done little to alleviate the man-made blight that all but cancels out the area's fabled sunshine.

The physician chosen for the post recently created by the Los Angeles Board of Supervisors will serve as an aide to County Health Officer Roy O. Gilbert, M.D. He says, "The position is intended to provide the County with an official viewpoint on the medical aspects of the air pollution problem. This will involve both clinical observations and statistical studies. It will also entail investigative effort in relation to research being conducted by others in the health implications of air pollution."

Although jokes dealing with the minor irritations of smog have become a staple of West Coast TV comedians, such humor is lost on those who are acquainted with smog's sometimes deadly effects. Surgeon General Leroy Burney of the Public Health Service has warned: "Investigators are finding a definite association between community air pollution and high mortality rates due to cancer of the respiratory tract."

Bringing Words to the Aged and Infirm

Libraries Find New Ways To Serve Elderly Patrons

In Racine, Wis., a bedridden oldster continues a life-long interest in reading by means of a ceiling projector for filmed books.

In Atlanta, Ga., physicians join with employment experts and government officials to give their time to a job clinic for senior citizens.

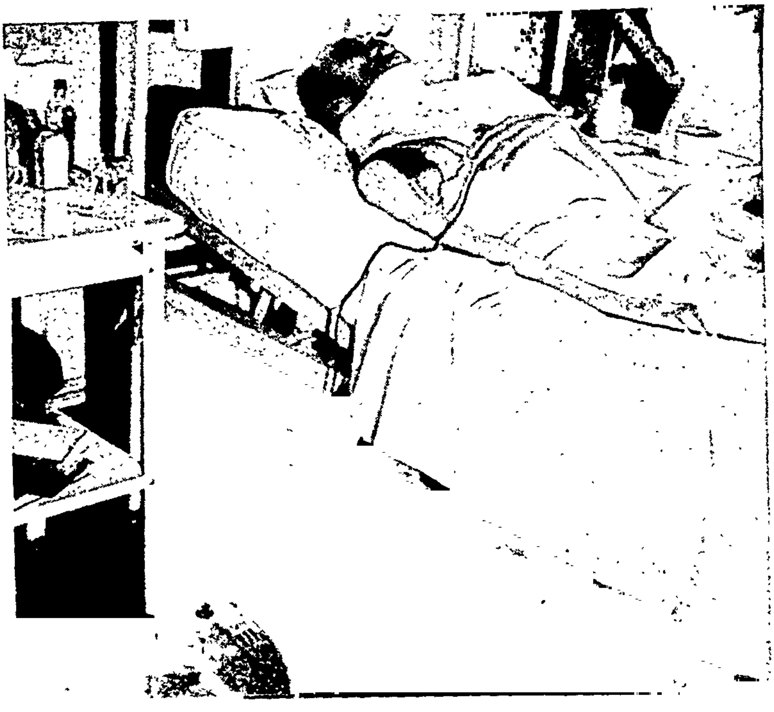
In Milwaukee, those who read to the housebound aged are offered a guide called "Let Us Read Aloud."

Despite the geographic spread these aids for the aging have one thing in common: They all are sponsored by libraries. The projects, and a number of similar ones, were explained by Milton Cummings, Ph.D., of the U. S. Office of Education, at a Washington meeting sponsored by the A. M. A. Committee on Aging.

In White Plains, N. Y., the public library—working with volunteers banded together as Friends of the Library—sends books and records to shut-ins, whether institutionalized or at home. The Huntington library in West Virginia accepts telephone orders for mailing books to readers free of charge.

A new library building in Montclair, N. J., has installed a self-service elevator for those in wheel chairs and a music area where groups can listen to records. The Free Public Library Commission of Wisconsin distributes a booklet entitled "The Advancing Years" listing books, pamphlets, reports, and surveys which should prove helpful to those working with older people.

Another pamphlet, "Books for Tired Eyes," is now in its fifth revision. Published by the American Public Library Association, it



Immobilized patient operates push-button control of ceiling projector, which makes more than 1,000 filmed books available to bedridden persons.

lists current books of interest printed in extra-large type for the benefit of older readers.

Most of these programs are adaptable to local conditions, Dr. Cummings said. Two similar Ohio plans deliver books directly to the sick and elderly both at home and in institutions. In Cleveland, the service is performed by librarian-specialists, but in Dayton, Ohio, the work is handled by volunteers.

At least one boon to the elderly came about partly by accident. The Chicago Public Library began a series of live and recorded noon concerts for Loop workers, only to find that the city's aged are now among the most enthusiastic listeners.

The Patient Stays Home in This Rehabilitation Plan

Medical teamwork is helping many chronically ill and disabled patients—most of them aged—return to at least partial self-care in New York's northern Westchester County. Team effort involves not only the patient's physician but a District Nurse and a physical therapist—and results in a plan of rehabilitative exercise to be carried out by the nurse in the patient's home. The program is sponsored by the District Nursing Association under a grant from the New York Arthritis and Rheumatism Foundation, which also makes available the help of a specialist in physical medicine as a consultant.

Here's how the program was explained in a recent issue of the Westchester County Medical Society's *Bulletin:* All patients on the nurse's schedule are reviewed by her for rehabilitative possibilities. Where restorative procedures seem indicated, the patient's physician is consulted. The patient is then given a rehabilitation evaluation by the plan's therapist, who consults with the physiatrist when necessary.

At this point, a plan of therapeutic procedures is worked out by the family physician, the therapist, and the nurse. The treatment agreed on is begun by the therapist and the nurse. In time the nurse is able to offer most treatment procedures, with the therapist dropping in occasionally to check on her progress. Once a month both nurse and therapist meet to discuss the patient's progress with a Health Department nutritionist and any social workers involved.

Rehabilitative services have been provided to more than 110 patients since the program was begun in 1956. Their median age was 64.5 years. Most suffered from stroke, degenerative diseases of the nervous system, arthritis, or hip fracture. Some of the rehabilitative procedures employed have been therapeutic exercise, heat application, moving from bed to chair, crutch walking, and the use of walkers.

Although few of the patients have been helped to the point of independence, nearly 70% show improvement, indicating that the restoration of even limited self-care is worth the effort expended.

Sometimes the little human attentions are as important to the "meals" recipient as the food the volunteers bring.

How Meals on Wheels Help the Shut-in

Tomorrow afternoon and every afternoon a station wagon will stop before a tenement building in Columbus, Ohio. Its driver will deliver one complete hot meal and enough cold food for two more to a shut-in incapable of providing adequate meals for himself. At almost the same time similar events will be taking place in Rochester, N. Y.; Philadelphia; and East Orange, N. J. These services are known as "Meals on Wheels."

Although they are similar in operation, the services have a wide variety of sponsors. In Columbus the service is operated by housewives led by a determined clubwoman. In Rochester and Monroe County it is being supervised by the Visiting Nurse Service and subsidized by the state health department. Philadelphia's "meals" program is operated by a settlement known as the Lighthouse, and in East Orange, the project is under the wing of 10 civic clubs.

It was in Philadelphia—spurred by the success of England's World War II plans to feed its bombed-out citizens—that "Meals on Wheels" had its American beginnings. Visiting nurses in the city's Kensington section pointed out to its Welfare Council that health breakdowns and hospital admissions resulting from grossly inadequate diets might be prevented by a plan that would offer adequate nutrition for those unable to provide it for themselves. The Council asked the Lighthouse to find an answer. The solution was "Meals on Wheels."

The Pattern Is the Same

Despite local variations all U. S. "meals" plans are essentially the same. Carefully planned hot meals are prepared in a central kitchen and delivered in warm containers. Accompanying the hot plate are sandwiches, cereals, fruits, and beverages to provide for much of the customer's caloric requirements for the rest of the 24 hours.

And customers they are, too. No client receives his meals free, although daily prices range from 30 cents to $2. Most plans provide a sliding scale of charges based on ability to pay. Deficits in operational budgets are covered in a variety of ways—foundation awards, service club donations, Community Chest appropriations, and fund-raising projects. Rochester's program will be subsidized through 1961 by the state health department as a demonstration project. In Columbus, "wheel" clubs meet monthly for card parties and donate their dues to the program.

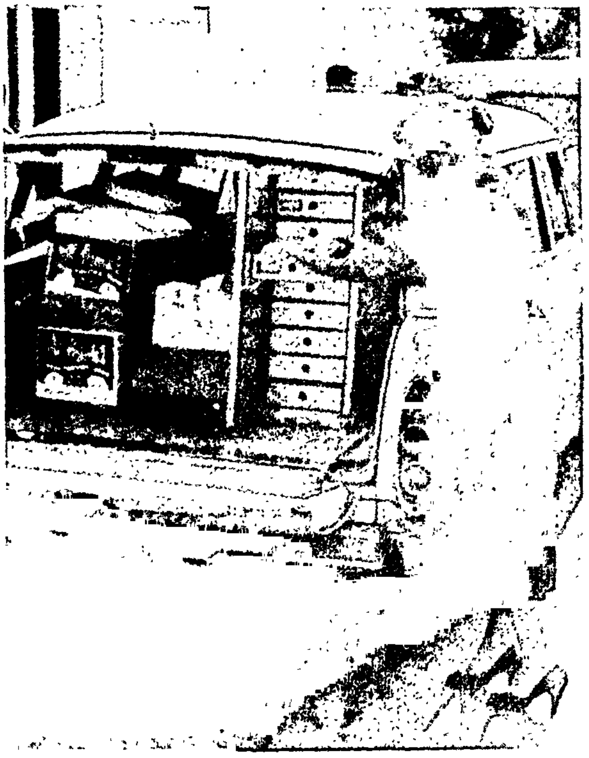
Physicians participate in some way in most of the plans. In many instances they are a source of referrals for the service. At least one service checks with its clients' physicians for special dietary orders. In Philadelphia Dr. Stanley Tauber acts as medical adviser to the Lighthouse project, which was given the 1956 Benjamin Rush award by the Philadelphia County Medical Society for its outstanding contribution to public health.

Three of the "meals" programs prepare their own food, hiring part-time kitchen help for the task. In Columbus arrangements have been made with two of the city's restaurants for hot food preparation. Many schemes have been tried for keeping food warm and palatable during delivery. Philadelphia volunteers put covered plates in reusable insulated bags which close with a metal clip. In Columbus meals are carried in a heated oven similar to that used by airlines.

Women and Teen-agers

Although some paid labor is used by each "meals" plan—usually cooks and kitchen help—reliance on volunteers is almost axiomatic. Not only do these unpaid workers keep costs down but they also furnish the friendly human contact that may be almost as helpful to the shut-ins as the food they bring.

In Columbus women members of "Meals on Wheels" substitute for the paid driver on week ends, allowing uninterrupted service through the week. In Rochester volunteers do almost all the work, from packaging meals to making deliveries. Two women are assigned to each car, one to drive and the other to make the actual delivery.



Airline-type carrier keeps food warm from kitchen to recipient in Columbus, Ohio.

In Philadelphia the Lighthouse program relies heavily on volunteers and has even attracted adolescent help. Teen-agers accompany staff drivers on their rounds and provide a measure of youthful company for "meals" recipients who would otherwise have little contact with the world outside.

All clients of these services have one thing in common: they would find it extremely difficult, if not impossible, to feed themselves adequately without the help of "Meals on Wheels." Most are elderly, handicapped by physical disability, and without family or friends to help.

Many newcomers joining the "meals" programs have been on a "tea and toast" diet for lengthy periods. "This is the first real food I've had in many a year," said one, and for the first few weeks of service, many complain of "too much food." Miss Izola Williams, Columbus nutritionist, says, "It appears they are unaccustomed to a full diet, or it is their custom to cut corners on food." The Columbus unit has found that if it can prevail on recipients to take food daily for three weeks, they will then maintain the schedule without urging.

One "meals" client—blind herself, and with a handicapped husband—was moved to write of her appreciation of the service, "We have been getting these meals for two weeks now, because of my husband's illness and my own handicap. It's wonderful not to have to eat burnt foods any more."

A.M.A. Disciplinary Committee

Toward "Heightening the Proper Practice of Medicine"

Are medical society grievance committees dealing adequately with the profession's tiny minority of errant practitioners? What is the number of this "tiny minority"? How might physicians better serve medicine's highest principles as well as the public by cracking down on the few "bad egg doctors" who are incompetent to the point of criminal negligence, who overcharge to the point of community revulsion, who evade their tax responsibilities to the point of court censure, or who run their practice while at the point of insanity or under drug addiction?

These and other gnawing questions came up for frank discussion last month in Salt Lake City at the first meeting of the new A. M. A. Medical Disciplinary Committee, which was created by the Board of Trustees during the Clinical Meeting in December. That session on April 16 represents the latest phase in a growing recognition by physicians that they must be their brothers' keepers in order to keep their art pure and holy. (See Medicine at Work, The Journal, April 5, 1958.)

In opening the conference, Dr. Raymond M. McKeown, a member of the Board of Trustees who serves as Committee Chairman, said: "The A. M. A. has become increasingly aware that someway, somehow, medicine should have something to say about the behavior of its practitioners. Those of us who have tried to bring about changes among the 3 to 5% of colleagues who are disreputable frequently lost out." Following are comments from other committee members:

"The 3 to 5% too often force us to live with their poor behavior, instead of we guiding them."

"We should launch our study on a more realistic approach to the fee situation, particularly as it relates to surgery."

"The fact that well over 90% of this nation's physicians are suffering from the antics of the other few per cent makes our mission strong."

"I consider physician overcharging of insurance companies the first goal for Committee study."

"Let's start gathering figures on what state medical license boards are doing to physicians convicted of unlawful acts."

"Many grievance committees are valuable for public relations but are not doing the job that needs to be done. Some are toothless watchdogs that bark but don't bite."

While calling for tighter control over the fringe of incompetent or dishonest physicians, the Committee as a whole by no means expressed any intent to undermine the profession's institution of grievance panels, 1,100 of which have been functioning in the United States since 1871—most effectively in the past decade, thanks to the diligence of more than 5,000 members both in and out of medicine.

One member of the new Medical Disciplinary Committee is Dr. James H. Berge of Seattle, who once headed his state society's grievance committee and is a founder and now chairman of Washington State's three-year-old Medical Disciplinary Board. The only body of its kind, this unit of state govern-

Physicians and attorneys chat informally (*left*) at luncheon between sessions of medicolegal conference in Salt Lake City, April 18. In front (*right*) are Gen. Frank Riter, representing American Bar Association, and Dr. U. R. Bryner (holding briefcase), president of Utah State Medical Association. Behind them are Dr. George M. Fister, member of A. M. A. Board of Trustees, and Ira A. Huggins, president of Bar Association of Utah. A. M. A. Law Division is scheduling another such regional series in 1961 (see Medicine at Work, The Journal, April 25, 1959).

Quotes on Conduct . . .

The whole profession should not be tarred with the same stick which should be applied to the few.

–Dr. Edward J. McCormick, on becoming A. M. A. President in 1953.

While it is never pleasant to find a colleague guilty and impose punishment, this is a responsibility falling on some of us.

–A. M. A. Judicial Council

Professionally, we doctors resemble dictators in alternating between complete disregard of criticism and exquisite sensitiveness to it.

–Alan Gregg, M.D., pioneer medical educator

If we individual physicians do not keep medicine's house in order, outside organizations–like hospitals or government–will do it for us . . . Our first responsibility is to our patients, and not to ourselves or our system of medicine.

–Dr. David B. Allman, Past-President of the A. M. A.

ment comprises a panel of physicians (elected by physicians) with power to censure, suspend medical license, or order outright revocation. Their rulings have been upheld in five revocation decisions taken to the state Supreme Court. "All of our actions," says Dr. Berge, "have been based on sound legal advice–not only from the board's counsel but from the state bar as well."

Cases cited by Dr. Berge at the Salt Lake City meeting last month covered unethical conduct involving nontherapeutic abortion, alcohol and narcotics addiction, income tax evasion, gross overcharging, and fraudulent billing to medical insurance companies. Penalties ranged from rebuke to revocation of license.

When the new A. M. A. Committee meets again in a few weeks, it is expected to draw up specific purposes and objectives, based on studies of the Washington board, various state medical practice laws, and related experience elsewhere in the United States. Dr. McKeown emphasized the Committee's basic motive when he told his colleagues: "We are here to find some acceptable method of heightening the proper practice of medicine without regimenting the profession."

Members of the A. M. A. Medical Disciplinary Committee are Drs. H. Thomas McGuire of New Castle, Del.; Paul G. Henley of El Dorado, Ark.; James H. Berge of Seattle; E. G. Shelley of North East, Pa.; and Raymond M. McKeown of Coos Bay, Ore., Chairman. Staff Secretary is Mr. C. Joseph Stetler of Chicago.

What Eight States Are Doing About Relative Value Studies

"We use our relative value study as a tool; we negotiate with it, and we'd have been in bad shape without it."

The speaker is Dr. John Rumsey of San Diego, Calif. The occasion is a Western-states regional meeting. His audience includes medical association officials from eight states west of the Rockies and a scattering of Midwesterners.

The group gathered in San Francisco last month at the request of the A. M. A. Committee on Medical Practices to talk about relative value studies and to review materials offered by the Committee to help state associations desiring to make such studies of their own (see Medicine at Work, The Journal, March 21, 1959.)

Dr. Rumsey was referring to the relative value study pioneered by the California Medical Association in 1956 after three years of work and the expenditure of about $50,000. He said, "We have used it in negotiations with Medicare, the unions, and in the county medical societies for grievance committee decisions."

Most of the state medical association representatives not only expressed an interest in pursuing relative value studies of their own, but in many cases had already begun the work and are borrowing heavily from California's experience and examples. Here is a round-up:

–Dr. William J. Reals of Wichita, Kan., reported that he and his Committee on Fees had spent 14 months preparing a relative value schedule for the Kansas Medical Society. He said, "The American public is committed to the budget system of paying its bills, and the public wants to budget its health expenditures too. Relative value studies have become a necessity."

–Dr. John DeTar of Milan, Mich., a member of the Committee on Medical Practices, said that the Michigan State Medical Society accepted the California study verbatim when it found itself needing one badly for negotiating purposes. He said: "We plan to follow up this action with a state-wide study of our own."

Arizona Yes–Colorado No

–In Arizona, according to Dr. Francis M. Findley of San Manuel, interest in a relative value study is high and the state association will probably make use of the California format. In the neighboring state of New Mexico interest in such studies is just beginning. Dr. John Corcoran of Albuquerque said a recently appointed committee expected work on the study to begin almost immediately.

–Colorado, on the other hand, has no plans for a relative value study, according to Dr. Cyrus Anderson. "Our physicians are opposed to a state fee

Theory of Relativity

Relative values is a rather high-sounding name for a simple concept:

—Values are unit designations assigned to medical procedures performed by the physician.

—Relativity is achieved by weighing each procedure according to the time, competence, effort, and experience required to perform it, as reflected by the physicians' customary charges.

For example, California's relative value study uses a unit value of 1 for a routine office visit, 2 for the first home visit, 10 for the first week of hospital care for a premature infant, and 20 for routine care of a well baby for one year (see Medicine at Work, THE JOURNAL, March 21, 1959).

schedule of any kind," he said. "We think we have a better arrangement in our flexible service plan which can be adjusted to a variety of income levels."

—Dr. James Buckley of Portland, Ore., said his state society's Prepayment Committee is working toward a revision of the Oregon Physicians' Service schedules, to be determined through a survey similar to that made in California.

—Dr. E. L. Calhoun of Aberdeen told the group that there is little interest in his state of Washington in the creation of a relative value study. He added, however, that the Committee's study is used in Washington as a check against fees.

—Nevada's 300 physicians will probably be surveyed soon. Dr. Arthur E. Scott of Reno said his state society's insurance committee had done some work in this field but is planning a more comprehensive job.

—Dr. Homer Smith of Salt Lake City said the Utah Medical Association already has a state fee schedule but that there is current interest in doing a relative value study as well.

Study Aids Available

Five A. M. A. publications developed to aid states planning relative value studies were displayed at the meeting. Included are a statement on the background and need for such studies (Relative Value Publication No. 1), a listing of code numbers and nomenclature based on the California model (RVP No. 2), a suggested format for the conduct of such a study (RVP No. 3), a check list of things to be done to make a study successful (RVP No. 4), and a series of questions and answers about such studies (RVP No. 5). Representatives of most states expressed the hope that the A. M. A. might be able to make the materials available in quantity for use in proposed studies.

Mr. Charles Williams of New York, representing the Health Insurance Council, said, "We are encouraged by California's development of a uniform nomenclature, and we are tending to use it as a replacement for our own. Many of our benefit schedules are out of date, and pay disproportionate amounts for services. Relative value studies will do a great deal for insurance companies."

Dr. Lester Bibler, chairman of the Committee on Medical Practices, told the group that theirs was the first in a series of informational meetings to be held on a regional basis. The second is being scheduled for the New England states on July 18 and 19.

A. M. A. Committee on Medical Practices meets in San Francisco prior to last month's regional meeting on relative value studies.

Dr. Reals of Kansas may have summed up the feelings of many physicians when he said, "If we don't make relative value studies of our own, someone else will. It may be done by our friends—but it might also be done by the government."

Medical Methuselahs—and Babies

One way to avoid the pitfalls that sometimes accompany retirement is to keep on working.

Though they don't specifically credit their happy longevity to their continuing practices, four Morganfield, Ky., physicians are nevertheless still at work. Each has passed the age of 85.

Reporting a recent interview with the four—Drs. H. B. Stewart, C. B. Graves, H. B. Allen, and J. W. Conway—the Evansville (Ind.) *Press* says none has any plans for retirement, although all have whittled down their working schedules.

Practicing for a total of 223 years leads to the accumulation of some pretty impressive statistics. One is that the four physicians have delivered just about as many babies as there are persons now living in the county—1,500.

The Law and the Laboratory —A Time to Remodel

In 39 states you can will your car to a friend, your real estate to your college, or your fortune to a pet canary, but you cannot bequeath your cornea to an eye bank or your body to a medical school. "In an era when physical science knows no limits," says Dr. Lester R. Dragstedt, "biology and medical advances are thwarted by jerry-built laws which were mainly enacted before the new medical possibilities appeared."

Dr. Dragstedt is president of the National Society for Medical Research (NSMR), which is cosponsoring the first National Conference on the Legal Environment of Medical Science. The meeting will be held on May 27 and 28 on the campus of the University of Chicago, its other sponsor. Scientists, legal scholars, and religious leaders are expected to attend.

Not only does the law make difficult the procuring of cadavers and other materials for use in research in anatomy, pathology, and organ transplantation but it remains cloudy in regard to the legal rights of and responsibilities toward human beings serving in trials of new medical treatments.

Next week's conference is an outgrowth of an NSMR committee established originally to investigate shortages of cadavers for anatomic studies. Those attending will be aiming at greater feats, however, and will attempt to reach agreement on ethical standards for the experimental use of human volunteers, cadavers, and laboratory animals. In addition, the conferees will seek to develop principles for a model legal code to govern research in medicine.

Participants will include representatives of groups affected by the differing practices, decisions, and laws affecting research which, says Dr. Dragstedt, "like Topsy—have just growed."

Award for "MD International"

A television documentary film portraying physicians abroad as medical ambassadors of good will has won the broadcasting industry's top honor.

The George Foster Peabody award went last month to "MD International," which was presented over NBC in 1958 by Smith Kline & French Laboratories in cooperation with the A. M. A. The production crew recorded activities of American physicians in private, missionary, military, foundation, and government practice. Countries visited included Japan, Korea, China, India, Indonesia, Iran, Turkey, Ethiopia, France, and Guatemala. (See Medicine at Work, THE JOURNAL, Sept. 7, 1958.)

Typical of these practitioners was Dr. Albert C. Holt, who said in Bombay, "We are representing the whole medical profession in America to these people. If we fail, American medicine fails in their eyes." A. M. A. President Gunnar Gundersen expressed it this way: "World peace cannot be attained until we build peace into the hearts and minds of men. We can add new meaning to the M.D. degree—Medical Diplomacy."

Some Wit and Philosophy at a Medical Meeting

Who says that all medical presentations are humorless drones of statistics, platitudes, and trivia? Below are some sample comments from two physicians who took part in a panel discussion at the American College of Physicians meeting in Chicago a month ago. A new feature of the five-day session was that business, civic, and nonmedical professional leaders were invited.

Dr. Irvine H. Page of Cleveland:

I am often asked, "Are we getting anywhere in research on heart disease?" It's like asking, "Are you getting anywhere with women?" It all depends on what you have in mind. In terms of dollars you have already gotten far more than you should have expected, but no horse can go as fast as the money you bet on it.

Femaleness seems to be much more than sex, as many of the richer males are finding out. Femaleness seems to assure that women, less likely to develop arteriosclerosis, will inherit this earth at least.

People will not give up something for nothing. When they were told not to smoke the consumption of tobacco went up about 6%. You know what happened when Mr. Volstead told them not to drink, and I haven't noticed a reduction in the birth rate.

Dr. Henry L. Bockus of Philadelphia:

The wise man does not accept retirement. He is not disturbed by it, for his life is, if anything, richer and happier than before. Actually he has not retired; he does not talk or think retirement.

No one can actually retire the person who won't withdraw. This person will continue to learn, and, above all, to render service to others, to the community, to his profession and country.

When does a philosopher become old? What is the age of wisdom? Someone has said that early indications of aging may simply be (1) when reading the newspaper, you turn to the obituaries before the sports page; (2) in the restaurant, you look at the menu before you look at the waitress; (3) in the station, you wait for the crowded escalator instead of using the empty stairs; and (4) your party is spoiled because you keep thinking how awful you will feel the next morning.

More Than Money

The reluctance of some older people to consult physicians concerning their health problems may not be a simple matter of economics.

Although about 85% of the persons in the over-65 age group cited in a recent survey said they had had some health complaint within the previous four weeks, only one in three had seen a physician. But among the two-thirds who did not call a doctor, only 3% said they delayed because of cost.

The survey was sponsored by the Health Information Foundation. George Bugby, HIF president, hazarded a guess on another possible reason for the failure to seek medical attention. He said, "Perhaps there is a feeling on the part of many older people that visiting a doctor or a hospital is tantamount to acknowledging an inability to cope with the inevitable illnesses of old age."

Some "Firsts" and "Specials" At the Atlantic City Meeting

What will be "different" about the A. M. A. scientific program next month? Quite a few things. When the 108th annual meeting opens for an estimated 15,000 physicians and 18,000 other persons there will be a number of new cooperative efforts, covering advances both in and out of medicine. The nonmedical fields include engineering, athletics, art, military affairs, and space technology. Even within the profession 14 other medical organizations will assemble for their own meetings around the time of the A. M. A. session, June 8 through 12.

Following are some of the "firsts" and "specials" of the scientific program:

–Seven sections will hold a joint symposium on June 11 in Convention Hall on progress in the management of childbirth. Six will meet together on June 10 to discuss hepatic diseases. Never before have more than two or three sections co-sponsored an A. M. A. symposium.

–For the first time there will be full-dress symposiums on hypnosis (June 11) and on medical problems in the jet and space age (June 9). In the recent past these subjects have been presented only in individual papers.

Other outstanding symposiums include one on blood diseases June 8, on viruses June 9, on aging June 10, and on cutaneous facial disfigurement (to be discussed more thoroughly than at any previous A. M. A. meeting) June 9. To top it off, 7 of the 21 sections of the scientific assembly this year are marking their 100th anniversaries—making next month's meeting even more "special."

(Details of the entire scientific program were published in the April 18, 1959, issue of The Journal.)

Look Again, Doctor

Museums Specialize Too—For Physicians and the Public

Richard P. Pratt

The list of modern means used to offer postgraduate medical education reads like a roll call of electronics—color television, two-way FM radio, motion pictures, tape and disk recordings, and transatlantic telephone hook-ups. Exposed almost daily to these technological advances, a hardworking doctor may easily overlook one method which has survived the test of centuries—the medical museum.

No man can clearly identify its origins, but the museum has been around for a long, long time. Alexandria was founded in 330 B. C. to extend Greek culture, and one of its early public buildings housed a museum containing laboratories, dissection chambers, botanical and zoological gardens, and living quarters for philosophers.

Today's medical museums may lack the breadth of Alexandria's, but they more than make up for this in depth. Tools for professional study and research are available—often close at hand—for the physician. And for the layman bent on adding to his knowledge of health, public museums offer many opportunities.

For the public, the outlook gets brighter all the time. Rapidly disappearing are the uninspired collections of specimens, models, and artifacts formidably enclosed in poorly lighted cases. In their place are being created highly entertaining, yet still instructive, exhibits which make effective use of modern materials and techniques to present anatomic and health information in dynamic forms.

For the physician the way is not so well prepared, but the inquiring mind will discover several notable collections that help to place medicine in historic perspective and provide a wealth of material for study and research.

An outstanding museum—and one quite different from most of its contemporaries—is the Hall of Fame and its accompanying School of History of Surgery and Related Sciences in Chicago. Housed in an impressive structure facing Lake Michigan, it was conceived by Dr. Max Thorek and is sponsored by the International College of Surgeons which he founded.

Skulls and Sculpture

Here the radiologist will find an operable x-ray machine more than half a century old, and the brain surgeon may view the perforated skulls of ancient Peruvians that show evidence of cranial surgery (trephination). Rare indeed is the physician whose understanding of his profession will not be enhanced by viewing the original model of the Carrel-Lindbergh artificial heart, reports in the handwriting of Freud, Pasteur, and Curie, and the surgical instrumentation of the ages.

Imhotep, the Egyptian physician who was elevated to full godhood, is memorialized in life-size sculpture in the Hall of Immortals as are such others as Hippocrates, Galen, Paré, Harvey, Morgagni, Semmelweis, and Lister. In the Hall of Murals, landmarks in the development of surgery have been executed in oils by Count Gregorio Calvi di Bergolo. Added to these are the historical displays of some two dozen of the world's free nations which have furnished rooms with materials illustrating the medical efforts of their physicians and national contributions to the arts of medicine and surgery.

Not content with its great but passive display of the wonders of the past, the School of History and Related Sciences periodically opens the building's main floor to audiences invited to hear prominent surgeons and educators discuss medicine's past, both recent and ancient.

In Washington

As might be expected, the nation's capital is the site of at least two collections valuable to the physician bent on education—either general or specific. The museum section of the Armed Forces Institute of Pathology will celebrate its centennial in 1962. Founded soon after Virchow's publication of the revolutionary concept of cellular pathology, it was formed originally as a repository for pathological specimens used in the training of Army surgeons. Its materials are now divided into public and professional collections. A wide range of mounted pathological specimens and gross tissue is available for professional study. The museum's collection of 500 microscopes is without equal in the U. S. and traces the instrument's evolution from crude origin to present electronic form. In addition, the museum has a selection of surgical and diagnostic instruments and even postage stamps of medical interest.

Ether to X-ray

Washington's venerable Smithsonian, storehouse for many national treasures, is another repository with great appeal for the physician. Although its collections are presented primarily for lay understanding, exhibits of professional value include a Peruvian skull still bearing the Western Hemisphere's oldest example of a surgical dressing, the patent office model of the W. T. G. Morton ether inhaler, and x-ray tubes used by Roentgen and Emil Grubbe.

Most of the Smithsonian's medical and pharmaceutical items are not isolated display objects but are parts of exhibits showing the evolutionary course of the subject. The museum includes col-

History of medicine through artistic eyes. These scenes are from Hall of Fame in Chicago. Paintings, *left* to *right*, depict honoring of Lister and Pasteur, early amputation, and trephination in prehistoric Peru.

lections of medical, dental, and pharmaceutical instruments; electrocardiographs dating from Dr. Frank Wilson's earliest efforts; a display of hearing aids "from cupped hand to transistor"; and such sidelight items as an early nursing bottle shaped like a woman's breast and made of glass.

Philadelphia

In Philadelphia, the Mütter Museum of the College of Physicians has attracted both medical students and physicians. The Mütter's educational appeal is chiefly historical. It was built around the pathology collection of Dr. Thomas Mütter, whose wet specimens were given to the museum in 1863. However, its displays also include a collection of skulls—some showing ancient trephination techniques used in Peru—, dislocated and fractured bones in various stages of repair, a display of clinical thermometers, 16th century surgical instruments, and a series on the evolution of the hypodermic syringe.

The Cambridge Contribution

The Warren Anatomical Museum in Cambridge, Mass., an adjunct of Harvard University, serves as a teaching collection for the Harvard Medical School, but its curator, Dr. Paul I. Yakovlev, hopes to see it become "a memorial of medical history at Harvard." In addition to its collection of normal and pathological bones and organs of man and animals, it also owns medical curios of historic interest for physicians.

Among these are the Crowbar Skull and the phrenological collection. The Crowbar Skull is that of Phineas Gage, foreman of a rock blasting gang, who accidentally fired a powder charge which drove a 13-lb. tamping iron into his cheek and out through the top of the cranium. The survival of the victim of this 1848 accident was a cause for wonderment for almost a century until the advent of frontal brain surgery in the late 1930's.

It was in this same era that phrenology enjoyed its vogue. The Warren Museum's collection of head casts was inherited from the Boston Phrenological Society after that group's interest waned in 1842. The unusual collection is comparable only to one in Paris.

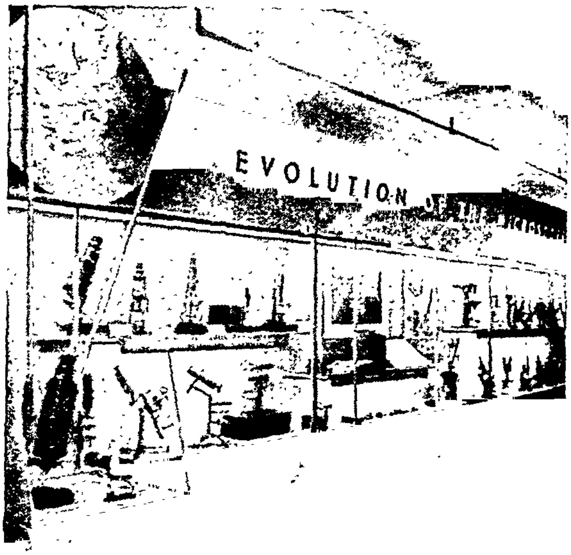


Exhibit of Armed Forces Institute of Pathology in Washington, D. C.

Mayo Foundation

As one of its many activities in Rochester, Minn., the Mayo Foundation operates a divided museum. One part serves to educate the public in matters of health; the other is a study and research collection open only to physicians, nurses, and dentists.

The professional exhibits are housed on a separate floor of the foundation's museum building and in the various hospitals. In addition to displays of medical and surgical instruments, models, photographs, and charts, the museum boasts more than 750,000 surgical and pathological specimens which are not exhibited but are available for study and research.

Education for the Public

Health museums for laymen got their start in early 20th century attempts to bridge the gap between lay and professional knowledge in Europe and Great Britain. In fact, German experts in health exhibit techniques were lured to the U. S. in the 1930's to aid in the preparation of the medical attractions which were popular at the great fairs held during that period in a number of the nation's major cities.

From these beginnings sprang the popular health museums that have emerged or are being considered in many U. S. cities. Cleveland's Health Museum was opened in 1940 with the blessing of the Academy of Medicine. In 1946, the Dallas Academy of Medicine—whose membership includes dentists, pharmacists, and hospital officials as well as physicians—sparked a drive that culminated in the Dallas Health Museum, which is maintained almost entirely by public subscription. The first

Second Life for Exhibits

Ever wonder what happens to exhibits shown at the A. M. A. Annual and Clinical meetings? Many pass into oblivion, but some graduate to the collections maintained by medical and health museums.

Refurbished and translated for nonprofessional audiences, several have been integrated into the lay collection of the Mayo Museum in Rochester, Minn. Many more are on display in the medical sections of the same museum.

One of the most popular of the technical exhibits from the 1958 meeting in San Francisco—Upjohn's giant-size model of a cell—is now on display for the hundreds of Chicagoans who visit the Museum of Science and Industry each day.

hospital to plan for and integrate a museum into its building plans was Lankenau in Philadelphia, opened to the public in 1953. Most recent addition to the museum ranks is the Kettering Foundation-sponsored Hinsdale Health Museum in Illinois, which was built in conjunction with a professional building.

Such single-purpose museums were pre-dated by a variety of health collections which were parts of general museums. These included the American Museum of Natural History in New York, the Museum of Science and Industry in Chicago, the Nebraska State Museum in Lincoln, and others in Buffalo and Toledo.

Dr. Bruno Gebhard, the pioneering curator of the Cleveland Health Museum, set the tone for the modern approach to such displays when he called them "museums, not mausoleums," a keynote that consigned poorly lighted, dust-gathering collections to oblivion and forecast the era of dynamic presentation using new methods and materials.

Models of mouths large enough to put your head into, life-size plastic body forms equipped with lighted organs and circulatory systems, tape recorded heartbeats, electrified models of the brain showing its functions, and bas-reliefs illustrating gestation from cell to child—these are the exhibits that well satisfy lay curiosity in matters of health, physiology; and bodily function and painlessly instruct in matters of natural law.

Looking Ahead

A small band of determined physicians has formed the Chicago Museum of Medical Science. As yet nothing more than a name, it was inspired by the late Dr. David J. Davis who, in 1929, wrote: "In Chicago, there should be a great medical and health museum planned in broad lines and covering every phase of historical medicine. . . . Here should be depicted the natural history of disease in all its phases, together with the efforts of man, successful and unsuccessful, to combat its ravages. . . . A medical museum properly organized, might serve the people in a medical way quite like the Art Institute serves them from the standpoint of art."

Proponents of the museum formed a nonprofit corporation in 1950 and won approval in principle from the Trustees of the American Medical Association. As described by Dr. Frederick Stenn, secretary of the group, the proposed museum would be "a treasury into and from which materials flow and are made available for loan anywhere in the country . . . a potent, vivacious, magnetic institution devoted not alone to collection and preservation, but to research and study . . . embodying the entire culture of medicine from its earliest days and pertaining to [its] every aspect."

Such a "medical visual aid institute," as it has been described by one of its backers, would search out treasures from "garret and cellar, the pawnshop, private collections, and refuse heaps." It would preserve and loan the best exhibits from medical meetings. "Every visual aid will be emphasized," says Dr. Stenn, "together with books, graphs, charts, EKG's, encephalograms, kinematograms, slides, anatomic and pathologic specimens, x-ray films, drawings, maps, photos, autographs, transparencies, models, dioramas, panoramas, statuary, coins, stamps, phonograph records, living demonstrations, models of the tonsil, larynx, esophagus, stomach, rectum, bronchus, and ear—both normal and pathologic—all seen through instruments specifically designed for their exhibition."

More Museums on the Way

The continuing public interest in health and medical history is being matched by the desire of organized medicine to help provide facilities to meet the demand.

Three decades of planning are expected to culminate next year in the opening of the Medical Museum of Wisconsin on the site of 19th century Fort Crawford at Prairie du Chien. It was here that Dr. William Beaumont performed his notable studies in digestion. Public contributions to the project will be accepted after the profession has had an opportunity to donate.

Sponsored by the State Medical Society of Wisconsin, the effort will include a restoration of the fort's military hospital and the construction of a museum building, curator's residence and workshop, and a pavilion. The *Wisconsin Medical Journal* reports plans to "discard the 'antique shop' approach, and create a series of living, changing exhibits involving dioramas, motion pictures, and periodically changing displays of an educational nature."

In Boston, meanwhile, construction of the central building of the projected $9,500,000 Museum of Science is now under way. The second of its seven floors will house the "Hall of Man, *Medicine*, and Public Health." The Medical Advisory Committee of the museum says the hall will promote public understanding of the structure and function of the human body, cite developments in the diagnosis and treatment of disease, and show in perspective the culture of man as his abilities have developed.

Aspirations such as these go hand in hand with medical progress. When man emerged from the self-imposed cultural exile of the Dark Ages, his search for knowledge resulted in "curiosity collections" of objects that intrigued but often mystified him. As he advanced—spurred by the often clandestine dissections and autopsies of the 16th century—his interest turned to anatomy and bodily function. These studies provided pathological specimens, and in the 18th century the famous Hunterian collections laid the groundwork for the modern medical museum.

And the medical museum, according to Sir Arthur Keith, former curator of the museum of the Royal College of Surgeons, is "an engine for the dissemination of culture."

THYROID NODULES AND THE FALLACY OF "ALL OR NONE" TEACHING

GUEST EDITORIAL

George Crile Jr., M.D.

ELSEWHERE in this issue of The Journal, page 405, is presented a reasonable plan of treatment for asymptomatic thyroid nodules. The line of thought therein contrasts sharply with the opinions of some who believe (and can prove by statistics) that nodules in the thyroid are of no consequence. It contrasts also with the opinions of others who believe (and can prove by statistics) that all thyroid nodules should be removed. The author of the plan believes (and can prove by statistics) that some thyroid nodules should be removed and that others should not.

The confusion of opinions and statistics in medical teaching is not limited to nodules of the thyroid. The treatments for gallstones, gastric ulcers, and polyps of the colon also have been subjected to the "all-or-none" principle. Yet to these and to many other problems there may be reasonable clinical and statistical approaches.

Although it is not known whether gallstones cause cancer of the gallbladder or are caused by cancers of the gallbladder, it often is said that in order to prevent the development of cancer all gallstones should be removed. In patients with the type of cancer of the stomach that clinically, radiologically, and cytologically resembles a benign ulcer, it is not known whether or not a month of medical treatment reduces the chances of surgical cure, yet some advise immediate resection of all gastric ulcers because of the possible presence of cancer. Despite our ignorance of the natural history of these and other diseases, some physicians boldly urge their patients to undergo major operations for the removal of lesions that either are causing no symptoms or could be treated successfully by medical means.

The opposite extreme in teaching may be equally ill-advised. When patients who are good surgical risks have both gallstones and persistent abdominal distress, it seems unreasonable not to advise them to have the gallbladder removed. When gastric ulcers recur or do not heal completely it seems unwise to persist in medical treatment. If a patient who is a good surgical risk has a definite polyp of the colon, it seems inconsiderate to subject him to the anxiety of repeated examinations when the polyp could be removed so simply. Between these extremes the best solution must lie. The appropriateness of this middle course is nowhere more apparent than in the treatment of the thyroid nodule.

It is difficult to believe that those who urge the removal of all thyroid nodules really believe that this course should be followed as a mass-production, public-health principle. Clinically, nearly 5% of all adults have palpable nodules in their thyroids. Pathologically, almost all persons beyond middle age have nodules. The surgeons who say that all thyroid nodules should be removed mean that most of the patients who are referred to them have the type of nodules that should be removed. They sometimes forget that they are asked to examine patients with nodules of only such a special nature that they are thought to be of clinical significance.

Although the feeding of desiccated thyroid does not often cause nodular goiters to disappear or to shrink significantly, it does stop most goiters from growing larger. It is cheap and easy to take. Doses of 1 or 2 grains (60 or 120 mg.) daily usually stop the growth of goiters and cause no side-effects. If instead of treating multinodular goiters with desiccated thyroid a total thyroidectomy is performed, the patient still must take thyroid for the balance of his life. Also, if subtotal thyroidectomy is performed the patient should take thyroid permanently if he is to avoid recurrence.

In laboratory animals, administration of thyroid hormone protects against all types of experimentally induced cancer of the thyroid. In man, many cancers of the thyroid have been shown to shrink or to disappear when desiccated thyroid is given. Both laboratory and clinical evidence suggest that feeding of desiccated thyroid affords as much protection against the development of cancer of the thyroid as does any operation short of total thyroidectomy.

An experienced observer who has followed nodules of the thyroid from the operating room through the pathology laboratory usually can suspect the presence of cancer in a thyroid nodule. A young patient with a hard area of infiltration in a

---

From the Department of General Surgery, The Cleveland Clinic Foundation, and The Frank E. Bunts Educational Institute, Cleveland.

lobe of the thyroid, a patient with a nodule and enlarged cervical lymph nodes, or an old patient with a hard, rapidly enlarging, infiltrating tumor should be suspected of having cancer. Soft, multinodular goiters, on the other hand, rarely are malignant.

It is dramatic to teach by generalization—to say that all thyroid nodules, all gastric ulcers, and all gallstones should be removed. Students enjoy this type of teaching; it is easy to learn. Clinical judgment, on the contrary, is hard to learn.

A physician is fortunate if in a lifetime he can study enough patients with one type of disease to attain a high order of judgment in this disease. That is why specialists are needed. The primary role of the surgical specialist in thyroid disease should not be to remove nodules, but to decide whether or not they need to be removed. The primary role of the internist specializing in thyroid disease should not be to treat thyroid nodules medically, but to decide which nodules should be treated medically and which should be removed. In decisions of this type, the judgment of well-trained surgeons and well-trained internists should be the same. Both surgeons and internists should be biologists at heart.

VENTRICULAR FIBRILLATION IN HEARTS TOO GOOD TO DIE

So much has been learned about ventricular fibrillation in recent years that in the future it may be possible to reduce its incidence. However, ventricular fibrillation is still a mystery in that it has no anatomic identity. It leaves no trace when it kills. It confuses the medical intellect by killing when it should not, when anatomic disease is mild and when life appears to be safe. It stops a good heart as readily as it does a damaged heart, in infants as well as in adults. It has no respect for sex or age. It kills with or without warning.

Nevertheless, positive gains have been made to prevent death and to restore life after ventricular fibrillation has occurred. One of the first encouraging signs came in 1899 from Prévost and Battelli, French physiologists, who described a method for the defibrillation of the heart of a cat in which a large electrode was placed on each side of the heart and an electric shock sent through the heart. The electricity made all the muscle fibers contract at the same time and when the current was broken the convulsive movements disappeared and the heart was ready to beat again. The heart of a dog is readily thrown into fibrillation by contact with an electric wire and it is just as readily defibrillated with use of the same electricity but more of it and spread over a larger area.

Cases of fibrillation and defibrillation were presented by motion picture to the American Surgical Association in 1937, along with records of patients whose hearts fibrillated during operation. The method for defibrillation also was presented. Ten years later, June 16, 1947, The Journal reported the case of the first human heart successfully shocked out of fibrillation with complete recovery. Application of the method was extended later to the wards and other parts of hospitals with success. It has been tried without success in concert halls and churches, on the roadside, and on golf courses. Regardless of where electric death occurs the requirements for success are the same.

Fibrillation of the ventricle in the human is produced by an electric charge made within the heart itself. The term "fatal heart attack" might be replaced by "self-electrocution of the heart." A checkerboard distribution of coronary artery blood produces these electric charges. They do not appear when the heart is uniformly deprived of oxygenated blood as in the "blue-baby" but when only part of the muscle is deprived of oxygenated blood as in the presence of an anomalous coronary artery. Children with anomalous coronary arteries cry out with anginal pain and die. Anginal pain and fibrillation are based on the same physiology. Generalized anoxia of the heart is tolerated even when it is severe; localized anoxia is painful and kills even when it is mild. The development of fibrillating charges is independent of an infarct. Conversion of oxygen differentials into electric charges requires further investigation. The old concept of "current of injury" implies that injury of muscle is involved when this current is produced. This concept is not valid. It implies that cyanosed muscle is injured muscle. The fact that a deeply and uniformly cyanosed heart is not injured and does not produce "current of injury" is evidence against this concept. A deeply cyanosed heart maintains electric equilibrium and while its contractions become weakened it does not fibrillate. The key point is the difference between localized anoxia and generalized anoxia.

Coronary heart disease is complex. Hearts with severe reduction in arterial inflow require more blood. Hearts in failure require better muscle. Hearts with adequate inflow but with checkerboard distribution require even distribution. These requirements dictate three approaches to treatment. The first and second are related, respectively, to structural disease in arteries and in muscle. Treatment of structural disease is a difficult research problem. The third yields to treatment by the creation of intercoronary channels. If these channels can be produced, then the treatment of this aspect of coronary heart disease will yield to that procedure which produces them. The physiology and treatment of this aspect of coronary artery disease deserve careful scientific analysis because positive steps in protection and treatment are in the realm of probability. They wait to be understood and applied.

ORGANIZATION SECTION

WOMEN'S AUXILIARY TO HOLD 36th ANNUAL MEETING

A presentation on survival medicine in national defense by Lieut. Col. Ingalls H. Simmons, M.C., will be one of the highlights of the 36th annual convention of the Woman's Auxiliary to the American Medical Association. More than 2,500 physicians' wives will attend the meeting which is being held in conjunction with the A. M. A. Annual Meeting June 8-12 in Atlantic City. Headquarters will be Hotel Haddon Hall. Colonel Simmons, who is director of the department of preventive medicine, Army Medical Service School, Fort Sam Houston, Texas, will speak Tuesday morning during the opening general meeting of the Auxiliary.

National committee meetings and round-table discussions will be held June 6-8 with formal opening of the convention slated for Tuesday morning. Business sessions on Tuesday and Wednesday will be devoted to state and national committee reports and discussions on current projects, ranging from automobile safety and community service to mental health and recruitment of medical personnel. Tuesday's luncheon in honor of Auxiliary national past-presidents will feature Aubrey Gates, Director of the A. M. A.'s Field Service Division, discussing medicine's legislative program.

During Wednesday's general meetings, Frank R. Burrows Jr., field service director of the Chicago Citizens Traffic Safety Board, will discuss the driver's responsibility in auto safety in his speech entitled, "You Can Get Blood Out of a Turnip." A report on alcoholism will be given by Dr. Marvin A. Block, Chairman of the A. M. A.'s Committee on Alcoholism, as part of the Auxiliary's mental health committee program. Speaker at Wednesday's luncheon honoring the President, Mrs. E. Arthur Underwood of Vancouver, Wash., and the President-Elect, Mrs. Frank Gastineau of Indianapolis will be Dr. Gunnar Gundersen, then immediate Past-President of the A. M. A. During this session the Woman's Auxiliary contribution to the American Medical Education Foundation will be given, and A. M. E. F. awards will be presented to the winning auxiliaries.

After the luncheon, two films will be shown: "Allied Medical Careers," produced by the Maricopa County (Arizona) Auxiliary and "Crusade for Freedom." In addition, Carol Lane of Shell Oil Company will present a demonstration on traffic safety. Election and installation of national officers will be held Thursday morning with adjournment scheduled for noon.

A postconvention workshop for national officers, directors, committee chairmen, state presidents, and presidents-elect will be held Friday morning to discuss upcoming programs and projects. Dr. Ernest B. Howard, A. M. A. Assistant Executive Vice-President, will speak on new A. M. A. activities, and George Cooley, Secretary of the A. M. A. Council on Medical Service, will discuss medicine's program on health care for the aged citizen. All Auxiliary members, their guests, and guests of physicians attending the A. M. A. Annual Meeting in Atlantic City may participate in all social functions and attend the general meetings of the Auxiliary. One of the outstanding social events will be the annual tea in honor of the Auxiliary President and President-Elect on Monday afternoon, sponsored by Pfizer and Company, a pharmaceutical firm. Local convention arrangements are under the direction of Mrs. David B. Allman of Atlantic City, General Chairman.

GOVERNMENT SERVICES

PUBLIC HEALTH SERVICE

International Fellowships.—International fellowships were awarded to 31 promising young medical scientists from Argentina, Austria, Belgium, Brazil, Chile, Colombia, Denmark, El Salvador, England, Finland, France, Germany, Holland, Peru, Sweden, Switzerland, and Uruguay. Administered by the National Institutes of Health, the program provides one year's postdoctoral medical research training in a United States institution of the recipient's own choosing. Each of the awardees holds a doctoral degree or its equivalent in one of the medical or related sciences and was formally endorsed by a committee of eminent scientists in his own country. Final selection of the recipients was made by a fellowship review board comprised of scientists at the National Institutes of Health. In operation since the beginning of 1958, this program is designed to foster the reciprocal exchange of scientific information and research techniques between the United States and foreign investigators.

Air Pollution Traineeships.—The Public Health Service has established a grants-in-aid program to increase the number, competence, and knowledge of professional personnel engaged in the prevention and abatement of community air pollution. A limited number of traineeships for training activities relating to the study of the effects, extent, assessment, or control of air pollution will be awarded to persons desirous of obtaining such specialized training and instruction during the 1959-1960 academic year.

A trainee must be a citizen of the United States or have filed a Declaration of Intent. In addition, a postdoctoral candidate must have a doctoral degree from a college or university offering a recognized degree. The regular (12 months) stipend for the postdoctoral trainee (to be prorated and paid on the basis of one-twelfth for each month of training) is $4,800. A stipend level differing from the above in cases of unusual need and on the basis of justification submitted by the applicant would be considered. An additional $360 for each legal dependent (as defined for federal income tax purposes) is allowed for a 12-month period, to be paid in equal monthly installments over the period of actual training. Stipends are not affected by a change of dependency status during the award period. Transportation costs at the rate of six cents per mile as computed by standard mileage charts are allowed to trainees between their present station and the training institution. No allowance is made for return travel, travel of dependents, or shipping charges for personal effects or household goods. Actual cost of tuition and fees will also be paid.

The traineeship is awarded for a period not to exceed 12 months. The trainee is expected to pursue a full-time training program. If support is desired for more than one year, special justification of the additional training should be furnished at the time the initial application is made. Support for additional training will, in all cases, depend on the availability of funds appropriated by the Congress for this program. The Public Health Service may terminate a grant before its expiration date on request of the trainee, on request of the training institution, or because of unsatisfactory performance, unfitness, or inability of the trainee to carry out the purposes of the traineeship. The training period must begin no later than 10 months after the date of notification of traineeship award. The award of a traineeship does not make the trainee an employee of the Public Health Service.

Applications for air pollution training grants-in-aid may be secured from any of the Regional Offices of the Public Health Service or from the Chief, Division of General Health Services, Bureau of State Services, Public Health Service, U. S. Department of Health, Education, and Welfare, Washington 25, D. C. Applicants wishing to start training during the 1959-1960 academic year should submit applications as soon as possible. Training grants will, however, be awarded as vacancies occur, and applications may be submitted at any time. Applications providing for training to start at other than the beginning of the normal academic year should preferably be submitted at least three months prior to the time the applicant wishes to begin training.

FOOD AND DRUG ADMINISTRATION

Public Warning.—*Persons who wear contact lenses* should avoid using a product called Barnes-Hind Wetting Solution, put up in 2-oz. dropper bottles by Barnes-Hind Ophthalmic Products, Inc., Sunnyvale, Calif., because it is contaminated with Pseudomonas aeruginosa, an organism which can cause blindness. The cleanser has nationwide distribution. Larger, one-pint containers are distributed to practitioners who prescribe or distribute contact lenses. The Food and Drug Administration said there would probably be no harmful effects from use in a normal, healthy eye but that dangerous infection may occur if any injury or infection is already present. Efforts are being made by the company and the government to recall outstanding stocks.

Preserving Fresh Fish.—The use of chlortetracycline to aid in keeping fresh-caught fish in sound condition was authorized by the Food and Drug Administration. The order sets 5 ppm as the maximum amount of the antibiotic that may legally remain on fresh-caught unprocessed seafood. Commercial fishermen will be allowed to use the drug on fresh-caught whole, headed, and gutted fish, shucked scallops, and unpeeled shrimp. It does not allow use of the antibiotic on processed seafood products, including fish cuts, steaks, and fillets, peeled shrimp, and shucked oysters. This drug has been used on uncooked poultry since 1955, and extensive data on its safety are available. A minute amount will remain in fresh seafood treated with the antibiotic and will not always be removed in cooking. Scientists and physicians have determined from available data and feeding tests that the prescribed amount of chlortetracycline can be consumed without harm, even to the few exceptional persons who may have developed a sensitivity to antibiotics. The law requires the labeling of treated seafood products to show that chlortetracycline has been added as a preservative. Commercial fishermen will use the antibiotic as a dip or in the ice as an aid to keeping their catch in sound condition. They may not use it in place of adequate refrigeration nor, because of its use, neglect to maintain thoroughly clean conditions aboard their boats.

Personal.—Charles G. Durbin, V.M.D., was appointed veterinary medical director of the Food and Drug Administration's bureau of medicine, succeeding the late Dr. John H. Collins. Fred J. Kingma, D.V.M., will succeed Dr. Durbin as associate veterinary medical director.

COUNCIL ON LEGISLATIVE ACTIVITIES

THE MEDICAL LEGISLATIVE DIGEST

The Medical Legislative Digest will be published about twice a month, while Congress is in session, by the Council on Legislative Activities. The purpose of the digest, which will take the place of the *Legislative Analysis* previously published by the Washington office, is to serve physicians and others who are directly concerned with or active in national medical legislative activities. The digest will include analyses of new congressional bills, reports on the status of pending medical legislation, and Association legislative activities and policies. It is suggested that copies of the digest be retained for future reference. The *A. M. A. News*, servicing the entire Association membership, will cover items of general interest on medical legislation which were formerly covered in the Washington letter. Since the purpose of the digest is to keep its readers well informed on congressional activities, suggestions for improvement will be most welcome.

Bill Analysis

Medical Expense Tax Deduction.—H. R. 6415 would amend the Internal Revenue Code in order to allow a deduction for all medicine and drugs when the taxpayer or his spouse has attained the age of 65. This bill would increase the medical deduction for taxpayers aged 65 and over. Under present law, a taxpayer in this age group, may deduct only the amount of medical expenses for medicine and drugs which exceed 1% of his adjusted gross income. The proposed law would authorize a deduction from gross income equal to the cost of all medicine and drugs if the expense incurred is primarily for the care of the taxpayer and his spouse. Representative Cramer (R., Fla.) introduced the bill April 15, 1959, and it was referred to the House Ways and Means Committee.

Study of Doctor Shortage in the United States.—H. R. 6417 would provide for the establishment of a commission to study the shortage of doctors of medicine in the United States. This bill would authorize a one-year study of the shortage of doctors in the United States. The study is to be undertaken by a 12-member group to be known as the Commission on the Doctor Shortage in the United States. Its members are to consist of two Senators, two members of the House of Representatives, two representatives from the executive branch of the government, and six members from private life. The medical profession would have representatives in the last group. The commission would give particular attention to (1) the policy of medical schools in limiting the number of student admissions; (2) the number of physicians graduated annually from medical schools in the United States; (3) the extent to which hospitals must seek foreign doctors to fill internships; (4) the number of U. S. citizens studying medicine in foreign countries who could not gain admittance to medical schools in the United States; and (5) the extent to which graduates of foreign medical schools are permitted to practice medicine in the United States.

The commission is to submit a final report to Congress not later than one year after the enactment of the Act. The report may contain recommendations and proposals for constitutional amendments, legislation, and administrative actions which in its judgment are necessary to carry out its recommendations. Representative Dorn (R., N. Y.) introduced the bill April 15, 1959, and it was referred to the Interstate and Foreign Commerce Committee.

Control of Radiation Hazards.—S. 1628 would provide for the vesting of primary responsibility for the protection of the public health and safety from radiation hazards in the Public Health Service of the Department of Health, Education, and Welfare. This bill authorizes the surgeon general of the Public Health Service to undertake research relating to radiation hazards, to make technical service available, to develop uniform standards of radiation protection, and to provide training for professional and technical personnel in matters relating to radiation hazard control. On introducing this bill the author stated that medical, industrial, and commercial use of x-ray machines and radioisotopes have increased the need for controls. The bill defines radiation hazard as "a source of ionizing radiation created or developed by man, including x-ray machines, nuclear reactors and their radioisotopic byproducts, high-energy particle accelerators, concentrated forms of naturally occurring materials, and the fallout constituents of nuclear weapons, which alone or in conjunction with other sources endangers or may endanger the public health."

After consulting with federal, state, and local agencies exercising responsibilities in connection with the control of radiation hazards, the surgeon general is to develop a comprehensive program in which he has the primary responsibility for the control and regulation of such hazards. The program

---

This is in essence the May 1 issue of *Medical Legislative Digest*.

is to also include recommendations for procedures to resolve any conflicts between the surgeon general and federal agencies arising out of the discharge of their various responsibilities in this area. The program shall also include recommendations with respect to (1) the role of the states in radiation hazard controls, (2) financing of federal and state activities under the program, and (3) providing assistance to the states in the development of model laws relating to the control of radiation hazards. The program is to be set forth in a report to be submitted to Congress no later than Feb. 28, 1960, together with recommendations for legislation to implement it.

A 15-member National Advisory Council on Radiation Hazard Control would be established to advise and assist the surgeon general. He would be chairman of the council. Other members would be the chairman of the Atomic Energy Commission, the Secretary of Defense, director of National Science Foundation, and 11 members appointed by the President from state and local agencies and public or private organizations. Senator Hill (D., Ala.) introduced the bill April 8, 1959, and it was referred to the Senate Labor and Public Welfare Committee.

Legislation Identical or Similar to Bills Previously Analyzed

Bill Number	Subject	Identical or Similar to	Page
H.R. 6248	Hospitalization; nursing home care and surgical services for Social Security beneficiaries	H.R. 4700	79 (L.A.)
H.R. 6393			
H.R. 6265	Control of radiation hazards	S. 1628	2 (M.D.)
H.R. 6325	Public health and professional nurse traineeship provisions of the Health Amendments Act of 1956	S. 731	46 (L.A.)

Status of Pending Legislation

Air Pollution Control Law.—The Air Pollution Control Law, S. 441, 86th Congress, was amended and favorably reported by the Senate Committee on Public Works on April 13, 1959. Existing law provides for a five-year program (expiring June 30, 1960) with an annual appropriation of 5 million dollars. S. 441, as originally introduced, would have made the Air Pollution Control Law permanent without any limit on appropriations. The amendment to the bill prepared by the Committee on Public Works would extend the law for another four years and authorize annual appropriations up to $7,500,000.

Keogh-Simpson Hearings Soon.—The Senate Finance Committee will probably commence hearings on H. R. 10, 86th Congress, the Keogh-Simpson bill, during the latter part of May. Unfortunately, H. R. 10 reached the Senate too late in the second session of the 85th Congress last year to permit Senator Byrd, Chairman of the Senate Finance Committee, to schedule hearings. If you have not already done so it is suggested that you contact your Senators and advise them of the reasons for your support of this legislation.

A. M. A. Legislative Activities and Policies

Government Employees Health Insurance.—The statement, outlining the Association's position and recommendations concerning S. 94, 86th Congress, was submitted on April 27th to the Post Office and Civil Service Committee of the Senate. This bill, which was analyzed on page 23 of the *Legislative Analysis,* provides for a voluntary health insurance program for federal governmental employees and their dependents.

Board of Trustees Acts on Proposed Legislation.—On April 26th, the A. M. A. Board of Trustees considered the recommendations resulting from the Feb. 28, 1959, meeting of the Council on Legislative Activities. The Board voted to reaffirm its approval of the Keogh-Simpson bill (H. R. 10, 86th Congress) and similar proposals encouraging the establishment of voluntary pension plans by self-employed individuals. It also expressed approval of a bill (H. R. 2549, 86th Congress) authorizing deductions from salaries of government employees for premiums to purchase accident and health insurance contracts.

In line with previous actions taken by the Association, the Board opposed the new Forand Bill (H. R. 4700, 86th Congress) and other legislative proposals which would expand medical coverage under the Social Security Act. These bills include proposals to lower the age requirement for disability benefits and to modify the definition of permanent and total disability. Other Board actions included opposition to proposed veterans' legislation extending presumptions of service-connection for various diseases and bills which would increase governmental control over the processing, distribution, and allocation of drugs.

Chairman of Advisory Committee on Aging Appointed

Former Congressman Robert W. Kean of New Jersey has been appointed chairman of the Advisory Committee for the White House Conference on Problems of the Aging. Although the conference will not take place until January, 1961, the advisory committee will start functioning in the near future. Congressman Kean will assume his duties May 1, and the first meeting of the committee will be held around May 15, 1959.

MEDICAL NEWS

CALIFORNIA

Competitive Examination for Epidemiologist.—The Los Angeles County Civil Service Commission has announced an open competitive examination for epidemiologist (M.D.) to act as advisor and consultant to the Air Pollution Control District, the Board of Supervisors, and all agencies working against smog. Minimum requirements include graduation from an approved medical school and completion of an internship approved by the Council on Medical Education and Hospitals of the American Medical Association; three years' experience in the diagnosis and control of communicable diseases, of which one year must have been in public health work; a California State Physician and Surgeon's Certificate at time of appointment; candidates must not have reached their 68th birthday on date of appointment; they must be citizens of the United States and bona fide residents of the county of Los Angeles by the last day for filing applications. Applications are open to both men and women. For information and applications write the Los Angeles County Civil Service Commission, 501 N. Main St., Los Angeles 12.

COLORADO

Pediatric Fellowships.—The department of pediatrics of the University of Colorado Medical Center, Denver, announced the availability in 1960 and 1961 of pediatric fellowships in allergy, infectious disease, hematology, and premature and newborn nursery. Applicants should be graduates of approved schools of medicine and should have completed at least one or more years of hospital training. Preference will be given to those who are in the course of completing the pediatric hospital training required for the examination of the American Board of Pediatrics. The fellowships, for one or two years, include fundamental laboratory research and clinical investigation, as well as training in clinical diagnosis and management. Inquiries should be sent to Dr. Henry K. Silver, University of Colorado Medical Center, 4200 E. Ninth Ave., Denver 20.

CONNECTICUT

Honor Fifty-Year Physicians.—Four physicians who have completed 50 years of active membership in the Connecticut State Medical Society were honored at the annual dinner of the society April 29. The physicians are Dr. Frank L. Phillips, New Haven; Dr. Charles H. Sprague, Bridgeport; Dr. Charles L. Dichter, Stamford; and Dr. Joseph N. Perreault, Danielson. Dr. Walter I. Russell, retiring president of the society, presented service pins to the 50-year members. The honor roll for 50 years of membership includes 32 other physicians who have previously received service awards. Three women physicians are members of the group: Dr. Jessie W. Fisher, formerly of Middletown and now of St. Petersburg, Fla.; Dr. Maude W. T. Griswold, Harwinton; and Dr. Laura H. Hills, formerly of Willimantic, now of Winter Haven, Fla.

DISTRICT OF COLUMBIA

Citations for Former Interns.—Former Freedmen's Hospital Interns who have been in the practice of medicine 50 or more years, will be honored at the 37th annual meeting of the Association of Former Interns and Residents of Freedmen's Hospital, at the Howard University School of Medicine, June 2-4. Among physicians to be cited are: Dr. William C. McNeill, Washington; Dr. Milton A. Francis, Washington; Dr. Ulysses G. B. Martin, Washington; Dr. George W. S. Ish Sr., Little Rock, Ark.; Dr. Thomas Coleman, Pittsburgh; Dr. John B. Hall, Chicago; Dr. William R. Johnson, Lancaster, Pa.; Dr. Frank W. Avant, Wilmington, N. C.; and Dr. Chester A. A. Gordon, Ark, Va.

FLORIDA

Plan Medical Center Expansion.—Metropolitan Medical Center is the name chosen by the Dade County Board of Commissioners for the new buildings and facilities developing around Jackson Memorial Hospital, the teaching hospital of the University of Miami School of Medicine, Coral Gables. The center will encompass expanded hospital and medical facilities. Under a 6-million-dollar bond issue, the expansion program of the county commission includes seven new additions to existing structures, four new buildings, modernization of present buildings, and an increased capacity of Jackson Hospital itself from 900 to 1,400 beds. In addition, a large area of land adjacent to the hospital has been secured by the commission to provide sites for other facilities, including the medical school's new research and education building; the research section is already under construction, scheduled for completion by the end of the year. A Veterans Administration Hospital with a capacity of 800 beds will be built nearby, and construction is planned for a National Children's Cardiac Hospi-

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

tal, a Baptist Hospital, a Cedars of Lebanon Hospital, and an Eye Institute. New headquarters for the area Blood Bank, the Miami Cancer Institute, and the Dade County Department of Health are also part of the future center plan. Already established in the Metropolitan Medical Center network are the United Cerebral Palsy Rehabilitation Clinic and the Crippled Children's Rehabilitation Center.

Open Audiology Clinic.—An audiology clinic was opened recently by the University of Miami School of Medicine, Coral Gables. It conducts diagnostic testing, including tests for recruitment, tone decay, articulation function, social adequacy index, tests for functional hearing loss, and electrodermal response audiometry for pure tone and for speech signals. In aural rehabilitation, Otto J. Menzel, director, stated that the clinic's primary emphasis will be on hearing aid evaluation and consultation. The clinic was established with the help of funds from the Miami Hearing Society and the United Cerebral Palsy Association.

ILLINOIS

Chicago

Meeting of Hospital House Staff Alumni.—The Michael Reese House Staff Alumni Association will hold its annual reunion on Wednesday, June 3, with an open house and luncheon held at the hospital during the day and a banquet at the Furniture Club in the evening (cocktail party, 6:30 p. m.). Former house staff and present attending staff members are urged to make reservations at once by writing the Michael Reese House Staff Alumni Association, 29th Street and Ellis Avenue, Chicago 16.

LOUISIANA

Dr. Goldsmith Given Nutrition Award.—Dr. Grace A. Goldsmith, professor of medicine, Tulane University School of Medicine, New Orleans, was presented the Osborne and Mendel Award for 1959 at the annual meeting of the American Institute of Nutrition April 15. The award, established by the Nutrition Foundation, Inc., and administered through the institute, is given each year for "outstanding recent basic accomplishments in exploratory research in the science of nutrition." Consisting of $1,000 and an inscribed scroll, the award was given to Dr. Goldsmith "for her contributions in the field of macrocytic anemias, especially studies on the specific roles of folic acid and vitamin B_{12}, in the clarification of the interrelationship of tryptophan and niacin in human nutrition, and in the field of protein malnutrition."

MASSACHUSETTS

Dr. Burwell Honored.—Dr. C. Sidney Burwell, Levine Professor of Medicine at Harvard University and the Peter Bent Brigham Hospital, Boston, received the John Phillips Memorial Medal of the American College of Physicians April 22. The medal, signifying "outstanding achievement in the field of internal medicine," was presented at the college's annual meeting. Dr. Burwell is the 21st physician to be honored with the award since it was established in 1929. The award honors Dr. John Phillips, of Cleveland, former assistant professor of therapeutics, Western Reserve University Medical School, who died in 1929. Dr. Amos Christie, of Nashville, Tenn., received the Phillips Memorial Medal in 1958.

MICHIGAN

Dr. Tourtellotte Receives Neurology Award.—Dr. Wallace W. Tourtellotte, assistant professor of neurology, University of Michigan Medical Center, Ann Arbor, received the S. Wier Mitchell Award at the annual meeting of the American Academy of Neurology, April 16. The $250 award acknowledged his original work on the chemistry of cerebrospinal fluid. It is given each year to a junior member of the academy "in recognition of his accomplishments and research." Dr. Tourtellotte was one of several U-M scientists who recently analyzed the fatty content of normal spinal fluid, reportedly for the first time.

Causes of Death.—The Michigan Department of Health reported that two changes occurred among the 10 leading causes of death in Michigan during 1958. Arteriosclerosis moved up from eighth to seventh spot, changing places with immaturity, and postnatal asphyxia and atelectasis replaced cirrhosis of the liver as the 10th leading cause. Deaths in Michigan last year totaled 65,460, according to the health department's provisional figures. This was a decrease of 484 from the comparable figure for 1957. As they have for the last half century, heart diseases ranked as the leading cause of death in Michigan last year. However, deaths from this cause were 144 fewer than the previous year. Other leading diseases that caused fewer deaths in 1958 than in 1957 were strokes, accidents, pneumonia and influenza, congenital malformations, and immaturity. Cancer, the second leading cause of death again in 1958, claimed 154 more lives than in 1957. Other causes that took more lives in 1958 than in 1957 were diabetes, arteriosclerosis, and postnatal asphyxia and atelectasis.

MISSOURI

Annual Lecture.—The 1959 Leo Loeb Lectureship, sponsored by Mu chapter of Phi Beta Pi Medical Fraternity, will be held at Wohl Auditorium, Washington University School of Medicine, St. Louis, Thursday afternoon, May 28. Dr. Jonathan E. Rhoads, of the department of surgery, Hospital of the University of Pennsylvania, will speak on "Preventive Surgery in the Field of Cancer—Studies on the Justification of Risk."

Personal.—Dr. Samuel L. Aspis, manager of the Veterans Administration hospital at Poplar Bluff was named manager of the VA hospital at Kansas City, Mo. He assumed his new post April 26.—— Dr. Robert L. Jackson, chairman, department of pediatrics, was appointed chairman of the Committee on Infant Nutrition by the Food and Nutrition Board of the National Research Council. This committee is charged with the responsibility of accumulating and interpreting scientific data available, defining the unsolved problems of infant nutrition, pointing out areas for future research, and advising the National Research Council on revision of recommended dietary allowances.

NEW YORK

Conference on Residency Problems.—Physicians receiving residency training in surgery at university hospitals met at the University of Rochester School of Medicine and Dentistry, May 7-9, at the first Conference of University Surgical Residents, designed "to afford an informal opportunity to explore common problems." The conferees heard from Dr. Seymour I. Schwartz, senior instructor in surgery at the University of Rochester, and from Dr. Donald G. Anderson, dean, UR School of Medicine and Dentistry, Dr. W. J. Merle Scott, chairman, department of surgery, and Dr. Theodore I. Jones, chief surgical resident. Discussions were held on clinical problems concerning portal hypertension, peptic ulcer and esophagitis, acute abdomen and pancreatitis, management of shock and trauma, and carcinoma and transplantation. A round-table discussion was held on the problems of surgical residency training at university hospitals.

Personal.—Dr. Robert L. Brown was appointed an assistant dean of the University of Buffalo School of Medicine. From 1952 until 1954, Dr. Brown served as director of professional services, The Armour Laboratories, Chicago. Recently, Dr. Brown was the medical and technical director for the Arner Co., Inc. of Buffalo.——Dr. Louis E. Daily, Norwich Pharmacal Company vice-president in charge of its Eaton Laboratories division, was named as a member of the Department of Defense advisory panel on medical sciences by Herbert F. York, Ph.D., director of defense research and engineering. The 21 civilian consultants appointed to the panel will provide advice on research, development, and engineering aspects of the defense program in the fields of aviation medicine, atomic medicine, psychiatry, and other pertinent medical sciences. Dr. Richard A. Kern, Temple University School of Medicine, is chairman of the panel.

New York City

Memorial Lecture.—The 23rd Adam M. Miller Memorial Lecture at the State University of New York Downstate Medical Center in Brooklyn was delivered April 20 by Dr. Charles S. Davidson, associate professor of medicine, Harvard Medical School, Boston. Dr. Davidson spoke on "The Mechanism of Death in Cirrhosis."

Dr. Horecker Appointed Department Chairman.—Bernard L. Horecker, Ph.D., was appointed professor and chairman of the department of microbiology of New York University College of Medicine. He succeeds Alwin M. Pappenheimer Jr., Ph.D., who became chairman of tutors of the department of biological chemistry at Harvard Medical School, Boston. Dr. Horecker came to NYU from the National Institute of Arthritis and Metabolic Diseases of the National Institutes of Health, where he was chief of the Laboratory of Biochemistry and Metabolism (1956-59).

NORTH CAROLINA

Grant for Program in Heart Research.—Bowman Gray School of Medicine, Winston-Salem, has been awarded a $568,480 grant by the National Institutes of Health to establish a program for training scientists in heart research. The grant, made by the Training Grants Section, National Heart Institute, Bethesda, Md., covers five years. Of the total, $260,000 will provide yearly stipends for trainees in all levels of the program. Purpose of the program is to prepare men and women for academic careers in all phases of cardiovascular research and teaching. It will be directed by a 10-man faculty committee headed by Dr. Harold D. Green, chairman, department of physiology and pharmacology. The departments of physiology and pharmacology, medicine, surgery, and radiology will have major roles; other departments will assist. Each trainee will be required to follow the complete program with some details individualized according to needs. The courses will include a broad survey of current cardiovascular knowledge, basic training in experimental techniques, participation in current research projects progressing to individual projects, and experience in "good teaching techniques." Trainees will work in all allied techniques and scientific disciplines, including anatomy, embryology, biochemistry, pathology, physiology, pharmacology, medicine, surgery, and radiology. Courses will be open to graduate physicians, holders of the Ph.D. degree who wish to specialize in the cardiovascular field, holders of the master's degree who are candidates for the Ph.D. degree, medical students who wish to drop out of medical school after the second year and resume their regular medical course later, and certain candidates for the master's degree.

OHIO

Dr. Sabin Named Award Recipient.—Dr. Albert B. Sabin, professor of research pediatrics, University of Cincinnati College of Medicine, and developer of an oral polio vaccine now undergoing tests, received the 1959 Howard Taylor Ricketts Memorial Award of the University of Chicago. Dr. Jonas Salk won the award in 1957. Dr. Sabin also is chief of the division of infectious diseases at the Children's Hospital Research Foundation in Cincinnati. He was invited to the University of Chicago campus June 29 to accept the award. The title of his Ricketts Lecture is "Oral Immunization Against Poliomyelitis with Live Attenuated Polioviruses—Developmental Problems, Present Status and Future Possibilities."

PENNSYLVANIA

Alumni Meeting in Atlantic City.—Dr. Gerald S. Backenstoe, 500 Chestnut St., Emmaus, Pa., has announced that the "University of Pennsylvania, Class of 1927M, will hold a reception and dinner Tuesday, June 9, 6 p. m., in the Jerry Backenstoe Suite, Shelburne Hotel," Atlantic City.

VIRGINIA

Conferences on Child Psychiatry.—Lectures and conferences in the fields of child psychiatry and child neurology were planned by professors in residence at the Lynchburg Training School and Hospital, Colony. Four such lectures were conducted Jan. 29-31. Subsequent speakers and lecture dates are as follows:

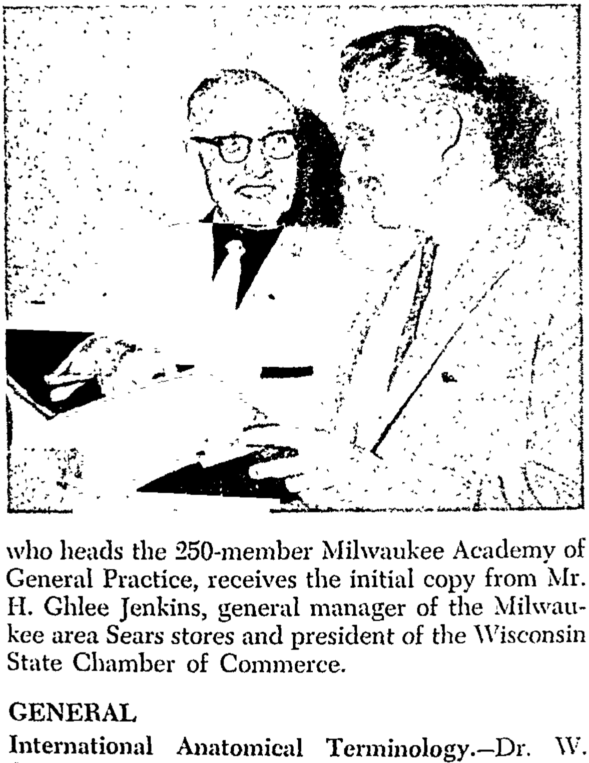
May 28-30, "Child Psychiatry," Dr. Wilfred C. Hulse, New York City.
July 30-Aug. 1, "Child Neurology," Dr. Walter O. Klingman, Galveston, Texas.
Sept. 24-26, "Child Psychiatry," Dr. Frederick H. Allen, Philadelphia.
Oct. 29-31, "Child Neurology," Dr. Sidney Carter, New York City.
Nov. 19-21, "Child Neurology," Dr. Paul M. Ellwood Jr., Minneapolis, Minn.

For information and registration write Mr. Arve Lee, Administrative Service Director, Lynchburg Training School and Hospital, Colony, Va.

WISCONSIN

Campaign for Medical Library.—A drive to solicit $600,000 from business and industry toward a new $850,000 medical library on the University of Wisconsin campus at Madison was launched by the University of Wisconsin Medical Alumni Association. The library will bear the name of former medical dean Dr. William S. Middleton, chief medical officer for the Veterans Administration, Washington, D. C. The special gifts drive was sanctioned by the University of Wisconsin and by the U. W. Foundation. Medical alumni already have raised some $200,000 from a national membership of more than 4,000 doctors and technicians, according to Dr. Mischa J. Lustok, Milwaukee, alumni general chairman. The campaign's general committee, headed by Mr. F. James Sensenbrenner, Milwaukee, includes the following: Dr. Einar R. Daniels, Milwaukee, president of the U. W. Medical Alumni Association; Dr. Abraham A. Quisling, Madison, president-elect of the U. W. Medical Alumni Association; Dr. Lustok; Dr. Albert G. Martin, Milwaukee, industrial chairman, medical alumni fund drive; and Dr. John Z. Bowers, Madison, dean of the University of Wisconsin Medical School.

Booklet on Business Aspects of Practice.—"The Business Side of Medical Practice," a 50-page booklet, will be presented to each family doctor in the Milwaukee area by the American Medical Association, in conjunction with the Sears-Roebuck Foundation. Here Dr. Stanley W. Hollenbeck, right, who heads the 250-member Milwaukee Academy of General Practice, receives the initial copy from Mr. H. Ghlee Jenkins, general manager of the Milwaukee area Sears stores and president of the Wisconsin State Chamber of Commerce.



GENERAL

International Anatomical Terminology.—Dr. W. Compere Basom, El Paso, Texas, in his paper on "Nomina Anatomica" presented at the Orthopedic Conference in New Orleans in January, said that this nomenclature is based more or less on the Basle Nomina Anatomica of 1895. The International Anatomical Nomenclature Committee published a revised "Nomina Anatomica" in 1956. In the original form the B. N. A. list of terms amounted to about 5,600. The new list numbers 5,640.

Dermatologists Meet in Atlantic City.—The 79th annual meeting of the American Dermatological Association, Inc., will be held June 1-4 at the Claridge Hotel, Atlantic City, N. J. A total of 28 papers are scheduled for presentation at the four scientific sessions. The presidential address, "The Dermatologist's Contribution to the Progress in Medicine," will be given by Dr. J. Lamar Callaway, Durham, N. C., to open the meeting. An awards presentation will close the meeting. For information write Dr. Wiley M. Sams, 25 Southeast Second Ave., Miami, Fla., Secretary.

Meeting on Investigative Dermatology.—The 20th annual meeting of the Society for Investigative Dermatology, Inc., will be held June 6-7 at the Ritz-Carlton Hotel, Atlantic City, N. J. A total of 37 papers are scheduled for presentation at four sessions. The presidential address, "Skin Cancer and Basic Research in Dermatology," by Dr. Hermann Pinkus, Monroe, Mich., will open the scientific sessions. Business and executive sessions will precede the morning programs. The dinner will be held June 6, 7 p. m. For information, write Dr. Herman Beerman, 255 S. 17th St., Philadelphia 3, Secretary-Treasurer.

British Psychiatrist Wins Award.—Dr. Maxwell S. Jones, Surrey, England, is the eighth winner of the American Psychiatric Association's $1,000 Isaac Ray Award, given annually to a psychiatrist or member of the bar "for furthering understanding between the two professions." As recipient, Dr. Jones will deliver a series of lectures on psychiatry and the law at George Washington University, Washington, D. C., in the next academic year under the joint auspices of the university's law and medical schools. Dr. Jones directs the Social Rehabilitation Unit at Belmont Hospital in Sutton. Since 1949 he has been on the Council of the Institute of Human Relations at Tavistock Clinic in London. The Award commemorates Dr. Isaac Ray, a founder of APA.

New Science Foundation Publication.—The National Science Foundation, Washington 25, D. C., published its first bimonthly issue of *Science Information News* for February-March. It was designed "to meet the need for reporting and exchanging news of worldwide activities in science communication and documentation." It is planned to develop the periodical so that it will provide service to all groups working in the various disciplines of science information. Although the first issue is slanted toward National Science Foundation activities, it is expected that most of the news will be material contributed by readers in later issues. Mr. Burton W. Adkinson is the head of the Office of Science Information Service, National Science Foundation.

Meeting of Tuberculosis Physicians.—The annual meeting of the American Academy of Tuberculosis Physicians will be held June 6 at the Ritz-Carlton Hotel, Atlantic City, N. J., with Dr. Marcio M. Bueno, New Bedford, Mass., president of the academy, presiding. A total of 19 papers are scheduled for presentation at the morning and afternoon sessions. At the luncheon session, the guest speaker will be Lt. Col. Stephen J. Berte, M.C., U. S. Army, Phoenixville, Pa., who will present "Experiences with Drug Combinations of High Dosages of INH, Daily SM, PAS, and Pyridoxine: An Evaluation of Clinical Results, the Recovery of Tubercle Bacilli from Resected Lung Specimens and Drug Toxicity Data." The presidential address at the luncheon session will be followed by the presentation of awards.

Endocrine Society Meeting.—On June 4-6 The Endocrine Society will hold its meeting at Chalfonte-Haddon Hall, Atlantic City. A total of 93 papers will be presented under the following section titles:

Thyroid.
Adrenal Cortical Syndromes—Steroid Metabolism.
Parathyroids: Pituitary Adrenal System.
Anterior Pituitary.
Estrogens and Androgens.
Pituitary Hormones—Neuroendocrine Mechanism.
Adrenal Gland.
Insulin and Diabetes.

Seventy-six papers will be read by title. The annual dinner will be held at Haddon Hall Hotel at which the presidential address will be given by Dr. E. Perry McCullagh. For information write Dr. H. H. Turner, 1200 N. Walker St., Oklahoma City, Okla., Secretary.

Rise in Traffic Deaths.—The National Safety Council reported that there was a 9% increase in March traffic deaths. The council said that meant 2,790 died in highway mishaps in March this year as compared with 2,560 fatalities for the same month last year. It was the third consecutive month to bring an increase after two years of almost unbroken reductions. The March figure brought the total for the first quarter of the year to 8,080—up 5% from last year's first quarter toll of 7,690. Disabling injuries in the first three months of 1959 were estimated by the council at 300,000. For three months, the council report showed deaths down in 16 states and up in 30, with three unchanged. Cities had a 2% increase in March, according to reports from 693 cities of more than 10,000 population. For three months, these cities showed a 3% increase from last year.

Chest Physicians Convene in Atlantic City.—The 25th annual meeting of the American College of Chest Physicians will be held June 3-7. The Silver Anniversary Convocation will be held the night of June 4. Postgraduate seminars on heart and lung diseases will be presented June 3. Round-table luncheons and "fireside conferences" are arranged, the latter to include the following foreign participants: Jose F. Valiente, San Salvador, El Salvador; Alberto Chattas, Cordoba, Argentina; Miguel Jimenez, Mexico City, Mexico; Leopoldo Molinari B., Lima, Peru; Mauricio Teichholz, Rio de Janeiro, Brazil; Carlos Zurita Gonzalez, Cabra de Cordoba, Spain. Three panel discussions are planned on "Treatment of Fungus Infections with Particular Reference to the Newer Therapeutic Agents," "Air Transport of Patients with Respiratory Disease," and "The Heart in Pulmonary Disease." Five symposiums are planned under the following titles:

Bronchogenic Carcinoma.
Pulmonary Tuberculosis.
Emphysema, Function Tests and Respiratory Aids.
Esophagus.
Primary Arterial Hypertension.

The annual president's banquet is planned for June 6, 7:30 p. m. Technical exhibits and a motion-picture program are arranged. A program of ladies' activities is planned. For information, write Mr. Murray Kornfeld, 112 E. Chestnut St., Chicago 11.

Cardiology Meeting in Philadelphia.—The eighth annual convention of the American College of Cardiology will be held May 25-29 at the Benjamin Franklin Hotel, Philadelphia, under the presidency of Dr. George W. Calver, Washington, D. C. The scientific sessions will include the following symposiums and moderators:

Some Cardiovascular Aspects of Space Medicine, Capt. Ashton Graybiel, M.C., U.S. Navy, Pensacola, Fla.
Biopathophysiology of Arteriosclerosis, Dr. E. Grey Dimond, Kansas City, Kan.
New Advances in the Radiologic Diagnosis of Heart Disease, Dr. Robert P. Glover, Philadelphia.
Use and Abuse of Cardiac By-Pass, Dr. J. Maxwell Chamberlain, New York City.
Management of Complications Attendant to Cardiac Surgery, Dr. Osler A. Abbott, Atlanta, Ga.
Recent Advances in Clinical Auscultation of the Heart, Dr. W. Proctor Harvey, Washington, D. C.
Phonocardiography and Chest Wall Vibrations, Dr. Aldo A. Luisada, Chicago.
Present and Future of Cineangiocardiography, Dr. Israel Steinberg, New York City.

The convention guest lecture will be given by Tage Astrup, Ph.D., Carlsbergfondets Biologiske Institut, Copenhagen, Denmark, the afternoon of May 28. Fireside conferences, a medical motion picture program, and scientific and technical exhibits are planned. The annual banquet will be held May 28, 7 p. m.

Congress on Rheumatic Diseases in Washington, D. C.—The second Pan-American Congress on Rheumatic Diseases will be held June 2-6 in Washington, D. C., under the auspices of the Pan-American League Against Rheumatism and organized by the Pan-American Committee of the American Rheumatism Association. Dr. Floyd S. Daft, director, National Institute of Arthritis and Metabolic Diseases, will open the meeting with an address. The official languages will be English, Portuguese, and Spanish. A total of 91 papers will be read at the plenary and concurrent sessions, with 74 papers to be read by title. Two panel discussions are planned: "Natural History of Rheumatic Fever" and "Variants of the Rheumatoid Syndrome," moderated by Drs. Gene Stollerman, Chicago, and Currier McEwen, New York City, respectively. Registration fee is $15, with service personnel and medical students, interns, and residents admitted free. For information, write Dr. Edward F. Hartund, 580 Park Ave., New York 21, Secretary.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Meeting on Legal Medicine.—The American Board of Legal Medicine, Inc., will hold its annual convention meeting at The Hotel Senator, South Carolina Ave., Atlantic City, N. J., Sunday, June 7, 9:30 a. m. The scientific papers, presented exclusively by members, are:

Medicolegal Aspects of Intervertebral Disk, Dr. Mortimer D. Abrashkin, Miami Beach, Fla.
Atomic Energy and the Law, Dr. Theodore W. Bisland, Dallas, Texas.
Medicolegal Aspects of Drunken Driving, Dr. Glenn W. Bricker, Levittown, Pa.
Medicolegal Role of the General Physician, Dr. Arthur H. Coleman, San Francisco.
Air Pollution and the Law, Dr. Sidney I. Franklin, Cleveland.
Space Medicine and the Law, Dr. George A. Friedman, New York City.
Arthritic Aggravation and Trauma, Dr. Louis J. Gelber, New York City.
Medicolegal Aspects of Myelography, Dr. Reuben Leass, Far Rockaway, N. Y.
Evaluation of Disability, Dr. Frank E. Leder, New York City.
Back Pain and Retarded Healing, Dr. Harold Lefkoe, Philadelphia.
Trends in Hospital Liability, Dr. Charles U. Letourneau, Chicago.
Medicolegal Aspects of Senility, Dr. Gustav Machol, Brooklyn.
Liability for Prenatal Injury, Dr. Harold W. Mayberger, Syosset, N. Y.
Medicolegal Aspects of Trauma to Chest, Dr. Jack Reiss, Coral Gables, Fla.
Should Your Patient Drive a Car?, Dr. Edward R. Richter, Lawrence, N. Y.
Urologist in Liability Field, Dr. Benjamin M. Shure, Brooklyn.

All interested persons are invited. There is no registration fee; register by writing to Secretary, Dr. George A. Friedman, 133 E. 58th St., Suite 410, New York 22.

CANADA

Dr. Cameron Receives Psychiatric Award.—Dr. Donald E. Cameron, of McGill University, Montreal, president of the Canadian Psychiatric Association and the past-president of the American Psychiatric Association, is the 1959 recipient of the $2,500 Samuel Rubin Award for outstanding achievements in mental health. The award was presented to Dr. Cameron April 17, by Dr. Paul R. Hoch, New York State commissioner of mental hygiene, and the first recipient of the award in 1957. Dr. Cameron was selected for the award by a professional committee under the chairmanship of Dr. Lewis R. Wolberg, dean of the Postgraduate Center for Psychotherapy, New York City. Dr. Cameron, who was born and educated in Scotland, was professor of neurology and psychiatry at Albany Medical College before going to McGill University in 1943 as chairman of the department of psychiatry.

Meeting of Biological Societies.—The second annual meeting of the Canadian Federation of Biological Societies will be held at the University of Toronto, Ontario, June 9-11. The program is arranged under the following section titles:

Adrenaline and Noradrenaline; Gross Anatomy and Histology; Toxicology; Biochemistry and Physiology; Circulation and Respiration; Histology and Embryology; Carbohydrates; Cancer; Cardiorespiratory and Environmental Physiology; Nutrition; Renal and Gastrointestinal Physiology; Nervous System and Muscle; Biochemistry; Biochemistry and Neurochemistry; Cholesterol Metabolism; Enzymes; Pharmacology; Endocrines; and the Biological Effects of Ionizing Radiation.

Business meetings for the Canadian Physiological Society, Pharmacological Society of Canada, Canadian Association of Anatomists, and Canadian Biochemical Society will be held the afternoon of June 10. A program of teaching films and exhibits are planned. For information write Dr. E. H. Bensley, Room 710, Montreal General Hospital, Montreal 25, Que., Canada.

LATIN AMERICA

Zoonoses Center in Argentina.—The Pan American Sanitary Bureau officially inaugurated its Pan American Zoonoses Center in Azul, Argentina April 25. The center, dedicated exclusively to studying the diseases transmitted between animals and man, is 185 miles south of Buenos Aires, in the province that shares the Argentine capital's name. It is administered by the bureau and financed by the Pan American Health Organization, the bureau's executive organ, and by technical assistance funds from UN/WHO and the Organization of American States. Dr. Benjamin Blood is director of the zoonoses center. In 1956 an agreement was signed between the Argentine Government and the Pan American Health Organization providing for establishment of the center and naming Azul as its site. The bureau is the world's oldest international health organization. It serves as WHO's Regional Office for the Americas.

FOREIGN

International Cytology Conference.—An International Cancer Cytology Conference, sponsored by the Instituto de Oncologia and the Ministry of Health, Madrid, Spain, the International Union Against Cancer, and the Pan American Cancer Cytology Society, will be held in Madrid, Sept. 22-26, 1960. President of the Conference is Dr. Julian Sanz Ibanez, director of the Madrid National Cancer Institute, and vice-presidents are Dr. James E. Ayre, Miami, Fla., Dr. Edmund V. Cowdry, of St. Louis, and Dr. J. Maisin, Louvain, Belgium. Dr. Angel Valle Jimenez has been appointed secretary general and Dr. Pierre-Hubert deWatteville of Geneva, Switzerland, is general program chairman. Representing the U. S. on the Advisory Council are

Dr. Alexander Brunschwig, Dr. Morris Fishbein, Dr. Ralph W. Jack, Dr. Locke L. Mackenzie, Dr. George O. Gey, Dr. Leonell C. Strong, and Dr. Richard W. TeLinde. The conference will focus world attention on cytology research and advanced methods of cancer control through early cytology diagnosis. For information, write the Pan American Cancer Cytology Society, P. O. Box 633, Coral Gables, Fla.

Section Meetings for Surgeons.—The International College of Surgeons announced the scheduling of 11 section meetings in Europe, Asia, and South America, with places and dates as follows: Thailand Section, Bangkok, May 21; German Section and German-speaking Federation, Hamburg, June 1-3; French Section, Lyons, June 19-21; The Netherlands Section, Amsterdam, July 25-26; Finnish Section, Helsinki, Aug. 8-9; Austrian Section, Vienna, Aug. 19-20; Brazilian Section, Santos, in September; China–Hong Kong Section, Hong Kong, Oct. 30; Thailand Section, Bangkok, Nov. 2; China–Formosa Section, Taipei, Taiwan, in December; India Section, Jaipur, Rajasthan, in December. For information, write to the Secretariat, International College of Surgeons, 1516 Lake Shore Drive, Chicago 10.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Written.* Various locations, July 8, 1960. Final date for filing application is January 8. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Dermatology: *Written. Several Cities,* Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. The final date for filing all applications is July 1, 1959. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *1959 Schedule—Written,* Oct. 19. Final date for filing application was May 1. *Oral.* For candidates on the West Coast, Portland, Ore., Sept. 9-12. Final date for filing application was March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application was March 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: Applications for certificates, new and reopened, Part I, and requests for re-examination Part II are now being accepted. All candidates are urged to make such application at the earliest possible date. Deadline date for receipt of applications is August 1, 1959. No applications can be accepted after that date. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6, Ohio.

American Board of Ophthalmology: *Oral.* Philadelphia, June 2-6; St. Louis, Oct. 6-10. *Written.* January 1960 in various cities. Applications for the 1960 written examination must be filed before July 1. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago. Jan. 19-21, 1960. The deadline for the receipt of application is Aug. 15, 1959. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Final date for filing application was April 1. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pediatrics: *Written.* January 1960. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation: *Written, Part I,* and *Oral, Part II.* Philadelphia, June 12-13. Final date for filing application was February 15. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Miami, Fla., Oct. 15-17. Final date for submitting case reports is July 1. Corresponding Secretary, Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Proctology: *Oral and Written.* Philadelphia, September. Final date for filing application was March 15. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: Chicago, Oct. 19-20; New York, Dec. 14-15; San Francisco, Mar. 14-15, 1960. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 was terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Examination.* Chicago, June 2-4. The deadline for filing applications was April 1. Washington, Dec. 6-9. Deadline for filing application is July 1. Candidates examined in Diagnostic Roentgenology may expect to be examined in Physics. A Special Examination in Nuclear Medicine (for diplomates in Radiology or Therapeutic Radiology) will not be given in June 1959. Candidates desiring this examination will be accommodated at the meeting of the Board in Washington, D. C. on December 5. Deadline for filing application is August 1. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Written* examinations (Part I) will be held on December 2, 1959 at various centers to be announced later. Candidates are urged to apply several months before completion of training requirements although the closing date for filing applications is August 1. Those completing training requirements after September 30 cannot be considered for the Part I examination in December of the same year. *Part II.* Columbus, Ohio, May 14-15. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, September 1959. Final date for filing application is July 1. *Oral.* September. Final date for filing application is July 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich.

American Board of Urology: *Written.* Approximately 25 cities throughout the country, December 4, 1959. *Oral-Clinical* and *Examination in Pathology.* Chicago, February 1960. Final date for filing application is Sept. 1, 1959. Sec., Dr. William Niles Wishard, 30 Westwood Rd., Minneapolis 26, Minn.

DEATHS

Adams, Walter Anderson Ⓜ Chicago; Howard University College of Medicine, Washington, D.C., 1926; assistant clinical professor of psychiatry, Chicago Medical School; fellow of the American Psychiatric Association; at one time practiced in Cleveland, where he was on the staff of the Lakeside Hospital; joint author of "Color and Human Nature"; associated with the Provident Hospital; on the courtesy staff of the Michael Reese Hospital, where he died March 7, aged 58.

Aud, Guy Ⓜ Louisville, Ky.; born Aug. 29, 1887; University of Louisville Medical Department, 1909; past-president and vice-president of the Kentucky State Medical Association; past-president of the Jefferson County Medical Society; in 1950 was presented with a medallion from the American Cancer Society for "distinguished service in cancer control," the first Kentucky doctor to receive the medallion; formerly chairman of the state executive committee of the Kentucky Division, American Cancer Society, and was regional medical director for fourteen Southeastern states for the society and a member of its national board of directors; in 1956 elected an honorary life member of the board of directors of the American Cancer Society, of which he was past-president; member of the founders group of the American Board of Surgery; member and formerly vice-president of the Southern Surgical Association; fellow of the American College of Surgeons; served as a member of the Southern Medical Association, Medical Research Commission of the State of Kentucky, Kentucky Surgical Association, and Phi Chi; veteran of World War I; surgical consultant to medical examining board, Selective Service Board from 1942 to 1946, and in 1947 received the Congressional Selective Service Medal; received a citation from the University of Louisville School of Medicine for 34 years of outstanding service; joined the faculty in 1915 and was professor emeritus of surgery; from 1911 to 1915 fellow in surgery at the Mayo Clinic in Rochester, Minn.; attending surgeon, Louisville General Hospital, St. Joseph Infirmary, and Kosair Crippled Children's Hospital; contributor of chapters in Cyclopedia of Medicine, Surgery, Specialties; resigned in September, 1958, as editor of the *Journal of the Kentucky State Medical Association;* died in St. Joseph Infirmary Feb. 27, aged 71.

Barclay, Robert Donaldson, Brookfield, Ill.; Dearborn Medical College, Chicago, 1904; for many years resident physician at the British Old Peoples Home; served on the staff of the Argo (Ill.) Hospital; died Feb. 4, aged 88.

Bigger, John Dinsmore, Bradenton, Fla.; University of Kansas School of Medicine, Kansas City, Kan., 1911; for many years a medical missionary in Korea; died Feb. 12, aged 77.

Blackwelder, Robert Guy, Hopkinsville, Ky.; Medical College of Virginia, Richmond, 1932; also a graduate in pharmacy; fellow of the American Psychiatric Association; superintendent of the Western State Hospital; formerly associated with the Huntington (W. Va.) State Hospital, Eastern Shore State Hospital in Cambridge, Md., and the Southwestern State Hospital in Marion, Va.; in 1956 appointed superintendent of the Andrew S. Rowan Memorial Home at Sweet Springs, W. Va.; died Feb. 1, aged 58.

Brand, George Douglas, St. Paul; Northwestern University Medical School, Chicago, 1917; certified by the National Board of Medical Examiners; veteran of World War I; died in New Britain (Conn.) General Hospital Feb. 23, aged 66.

Bresee, Paul H., Los Angeles; University of Southern California College of Medicine, Los Angeles, 1892; served on the staffs of the Hospital of the Good Samaritan and Angelus Hospital; died Feb. 5, aged 87.

Bridges, William Arthur Ⓜ Lutherville, Md.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1915; member of the American Trudeau Society; served as medical superintendent of the Eudowood Sanitarium in Towson, where he died Feb. 23, aged 78.

Brown, Thomas Ponder Ⓜ Thomasville, Ga.; University of Georgia Medical Department, Augusta, 1914; veteran of World War I; died Feb. 22, aged 78.

Bouvy, Leo Benedict Ⓜ La Grande, Ore.; University of Pennsylvania School of Medicine, Philadelphia, 1920; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow the American College of Surgeons; past-president of the Oregon State Medical Society; on the staffs of St. Joseph's Hospital and Grande Ronde Hospital; died in Los Angeles Feb. 18, aged 66.

Ⓜ Indicates Member of the American Medical Association.

Chandler, James Robert Ⓜ Magnolia Springs, Ala.; Birmingham Medical College, 1909; veteran of World War I; district physician for the Tennessee Coal and Iron division of the U. S. Steel Corporation for 35 years; past-president of the Bessemer (Ala.) Rotary Club; died in South Baldwin Hospital, Foley, Feb. 18, aged 76.

Christian, William I., Springfield, Ohio; Medical College of Ohio, Cincinnati, 1891; died in the Knights of Pythias Home Hospital Feb. 16, aged 93.

Clark, Fred Orlin Ⓜ Syracuse, Ind.; Indiana University School of Medicine, Indianapolis, 1931; president of the Syracuse Planning Commission; veteran of World War II; died Feb. 27, aged 53.

Conner, Robert Everett Ⓜ Hickory, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1893; on the staff of the Washington (Pa.) Hospital, where he died Feb. 22, aged 92.

Cooper, John Elbert Ⓜ Battle Creek, Mich.; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1902; fellow of the American College of Surgeons; past-president of the Calhoun County Medical Society; on the staffs of the Leila Y. Post Montgomery and Community hospitals; died in the Battle Creek Sanitarium Feb. 11, aged 81.

Dodson, Austin Ingram Ⓜ Richmond, Va.; born April 16, 1891; Medical College of Virginia, Richmond, 1916; specialist certified by the American Board of Urology; served as president of the Virginia Urological Association and the Richmond Academy of Medicine; member of the American Association of Genito-Urinary Surgeons and the American Urological Association; fellow of the American College of Surgeons; professor of urology at his alma mater; on the staffs of the Medical College of Virginia, Hospital Division, St. Elizabeth's Hospital, and St. Luke's Hospital; author of "Synposis of Genitourinary Diseases" and "Urological Surgery"; died Feb. 21, aged 67.

Everingham, Sumner Ⓜ Oakland, Calif.; Columbia University College of Physicians and Surgeons, New York City, 1910; member of the founders group of the American Board of Surgery; veteran of World War II; associated with the Children's Hospital of East Bay, Peralta and Samuel Merritt hospitals; died March 4, aged 73.

Fairchild, Fred Ross Ⓜ Woodland, Calif.; Cooper Medical College, San Francisco, 1902; member of the founders group of the American Board of Surgery; member of the Western Surgical Association; fellow of the American College of Surgeons; served as health officer of Yolo County; veteran of World War I; a founder and member of the honorary staff of the Woodland Clinic Hospital; died Feb. 22, aged 83.

Gallivan, William Francis, Buffalo; University of Buffalo School of Medicine, 1909; fellow of the American College of Surgeons; formerly secretary of the Western New York Surgical Association; member of the medical advisory committee of Blue Cross and Blue Shield; associated with the Millard Fillmore Hospital, Edward J. Meyer Memorial Hospital, and the Emergency Hospital of the Sisters of Charity, where he died Feb. 20, aged 73.

Gelderman, Frederick Herman, Tucson, Ariz.; Chicago Homeopathic Medical College, 1900; died March 9, aged 82.

Gerson, Max Bernhard Ⓜ New York City; Albert-Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1909; author of "Cancer Therapy: Results of Fifty Cases"; died March 8, aged 77.

Greenberg, David Ⓜ New York City; University and Bellevue Hospital Medical College, New York City, 1913; past-president of the Bronx County Medical Society; veteran of World War I; for many years police surgeon; associated with the Lebanon and Jewish Memorial hospitals; consulting physician at Morrisania Hospital; died Feb. 25, aged 71.

Greene, Luther D., Richmond, Mo.; University Medical College of Kansas City, Mo., 1891; formerly member of the state legislature; for eight years on the board of regents of the Northwest Missouri State College, Maryville; died Feb. 13, aged 91.

Hombach, William Henry Sr. Ⓜ Grand Island, Neb.; John A. Creighton Medical College, Omaha, 1913; veteran of World War I; on the staffs of the Lutheran Hospital and St. Francis Hospital, where he died Feb. 20, aged 69.

Huth, Leo, Follansbee, W. Va.; (licensed in West Virginia in 1902); veteran of the Spanish-American War and World War I; died in the Veterans Administration Hospital, Aspinwall, Pa., Feb. 22, aged 80.

Imler, Daniel Canning, Willow Grove, Pa.; Jefferson Medical College of Philadelphia, 1927; on the staff of Abington (Pa.) Memorial Hospital; died Feb. 26, aged 59.

James, William Alfred Ⓜ Chicago; Northwestern University Medical School, Chicago, 1911; served on the faculty of his alma mater; on the staffs of the Garfield Park Community and Bethany hospitals; at one time a staff physician of Commonwealth Edison Company; died March 3, aged 73.

Julien, Eric Alfred Ⓜ Turlock, Calif.; Northwestern University Medical School, Chicago, 1911; first president of the staff of the Emanuel Hospital; died Feb. 24, aged 74.

Keyes, Edward Clarence, Salina, Okla.; University of Nebraska College of Medicine, Omaha, 1902; died in the Grand Valley Hospital, Pryor, Feb. 19, aged 81.

Knopf–Bravin, Rita, Pittsburgh; Woman's Medical College of Pennsylvania, Philadelphia, 1922; examining physician of Juvenile Court and school medical inspector for the city health department; on the dispensary staffs of Shadyside and Passavant hospitals; died in the Shadyside Hospital, March 9, aged 61.

Lewis, Lloyd Griffith Ⓜ Washington, D. C.; born in Remsen, N. Y., Nov. 10, 1902; Johns Hopkins University School of Medicine, Baltimore, 1928; clinical professor of urology at Georgetown University School of Medicine, where he was associate professor of urology from 1946 to 1948 and professor of urology from 1948 to 1953; instructor, associate and assistant professor of urology at his alma mater from 1933 to 1942; for many years associated with Johns Hopkins University Hospital in Baltimore; served on the staffs of the Georgetown, Doctors, and Walter Reed General hospitals; veteran of World War II; awarded Legion of Merit in February, 1946; consultant in genitourinary surgery to the Secretary of War; specialist certified by the American Board of Urology; member of the American Urological Association; fellow of the International College of Surgeons; died March 2, aged 56.

Long, Vann McKee Ⓜ Winston–Salem, N. C.; North Carolina Medical College, Davidson, 1906; county coroner; past-president of the North Carolina Urological Association; honorary staff member of the City Memorial Hospital; died Feb. 19, aged 76.

McConnell, Seth Anderson Ⓜ Major, U. S. Army, retired, Galveston, Texas; University of Texas School of Medicine, Galveston, 1916; also held a degree in law; veteran of World War I, and received the Croix de Guerre from the French government; served in the U. S. Army from 1916 to 1929, retiring with the rank of major; formerly associated with the Austin (Texas) State Hospital and the East Louisiana State Hospital in Jackson, La.; died Nov. 18, aged 72.

MacKowiak, Felix A. Ⓜ Chicago; Loyola University School of Medicine, Chicago, 1919; served as health commissioner of Riverside, Ill.; associated with Cook County Hospital and St. Mary of Nazareth Hospital, where he was past-president of the staff, and where he died March 5, aged 64.

Matikiewicz, Joseph Peter Ⓜ Thompson, Pa.; St. Louis University School of Medicine, 1937; veteran of World War II; died in the Binghamton (N. Y.) City Hospital Feb. 14, aged 52.

Murphy, John Harvey Ⓜ Moline, Ill.; Northwestern University Medical School, Chicago, 1906; veteran of World War I; honorary member of the medical staff, Hammond–Henry District Hospital in Geneseo; treasurer of the Moline Horticultural Society; died in the Moline Public Hospital Jan. 29, aged 81.

Morrissey, Paul Gunkle Sr. Ⓜ Nashville, Tenn.; University of Nashville Medical Department, 1902; member of the American Urological Association; fellow of the American College of Surgeons; associated with the Nashville General Hospital, where he was past-chairman of the board of commissioners, and Vanderbilt University Hospital; member and past-president and for many years secretary treasurer of the staff of St. Thomas Hospital, where he died Feb. 1, aged 78.

Nelson, William Thomas, Cincinnati; Howard University College of Medicine, Washington, D. C., 1904; died in St. Mary's Hospital Feb. 15, aged 82.

Newmayer, Solomon Weir Ⓜ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1899; served on the faculty of his alma mater; formerly medical inspector of the bureau of health and medical supervisor for the board of education; consulting eye physician for Selective Service during World Wars I and II; associated with Mount Sinai Hospital, Wills Hospital, and the Hospital of the University of Pennsylvania; died in the Lankenau Hospital March 1, aged 81.

Nystrom, Elmer Edwin Ⓜ Peoria, Ill.; Northwestern University Medical School, Chicago, 1909; member of the American Academy of General Practice; formerly vice-president of the Mississippi Valley Medical Society; veteran of World War I; associated with St. Francis Hospital and the Methodist Hospital, where he died Feb. 23, aged 74.

Olds, Wilson Albert Ⓜ Colville, Wash.; Washington University School of Medicine, St. Louis, 1908; died in Mount Carmel Hospital Jan. 5, aged 75.

O'Leary, John Jeremiah Ⓜ Olympia, Wash.; University of Michigan Medical School, Ann Arbor, 1916; veteran of World War I; member of the staff of St. Peter's Hospital, where he died Feb. 16, aged 67.

Orsburn, Roy Ⓜ Sebree, Ky.; University of Louisville (Ky.) Medical Department, 1910; served as health officer of Webster, Muhlenberg, Fleming, Garrard, Lincoln, Simpson, Allen, and Marion counties; past-president of the Green River Valley Public Health Association; died Feb. 4, aged 79.

Ott, Howard, Portland, Pa.; Maryland Medical College, Baltimore, 1909; served as president of the school board and postmaster; chief burgess of Portland; member of the staff of the General Hospital of Monroe County, East Stroudsburg, where he died Feb. 14, aged 77.

Parker, Harry Lee Ⓜ Rochester, Minn.; born in Limerick, Ireland, Feb. 20, 1894; University of Dublin School of Physic, Trinity College, Dublin, Ireland, 1918; volunteered for service in the Royal

Army Medical Corps of England in April, 1918, and served in France; in June, 1919, was released from service with the grade of second lieutenant; came to Rochester, Minn., in November, 1919, as a fellow in surgery of the Mayo Foundation; in 1921 transferred his major interest to neurology; appointed to the staff of the Mayo Clinic as a consultant in neurology on Jan. 1, 1925, and instructor in neurology in the Mayo Foundation, Graduate School, University of Minnesota; subsequently was advanced to assistant professor and associate professor; became a citizen of the United States in 1927; returned to Ireland on Aug. 1, 1934, and practiced neurology and psychiatry in Dublin; appointed honorary professor of neurology in Trinity College, and was staff physician to the Richmond, Whitworth, and Hardwicke hospitals, the Stewart Institute for Feebleminded Children, the Bloomfield Mental Hospital, and the Royal Hospital for Incurables; consulting neurologist to the Meath, Mercers, and Orthopedic hospitals in Dublin; returned to Rochester in July, 1945, as a consultant in neurology in the Mayo Clinic and professor of neurology in the Mayo Foundation; specialist certified by the American Board of Psychiatry and Neurology; member of the American Neurological Association, Central Neuropsychiatric Association, British Medical Association, Royal Academy of Medicine in Ireland, the Association of British Neurologists, Central Neuropsychiatric Association, Minnesota Society of Neurology and Psychiatry, and the Alumni Association of the Mayo Foundation; fellow of the Royal College of Physicians of Ireland and of the Royal Society of Medicine of England; past-president of the Royal Academy of Medicine in Ireland and of the Dublin University Biological Association; author of "Clinical Studies in Neurology"; died in St. Mary's Hospital March 1, aged 65.

Pritchett, Asa Belvin Ⓜ San Antonio, Texas; University of Texas School of Medicine, Galveston, 1917; member of the staffs of Santa Rosa, Nix, and Baptist hospitals; died Feb. 18, aged 67.

Reece, Herbert Bowen, Sea Bright, N. J.; Albany (N. Y.) Medical College, 1905; member of the American Urological Association; died Jan. 6, aged 77.

Rhodes, Nelson M. Ⓜ Urbana, Ohio; Cleveland Homeopathic Medical College, 1906; past-president of the Champaign County Medical Society; served on the board of education for 12 years, eight of which he was president; died in the Mercy Hospital Feb. 16, aged 78.

Rogers, Jennie Maud Thomas Ⓜ Canton, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1898; member of the American Academy of General Practice; associated with the Graham Hospital; died in the Carle Memorial Hospital, Urbana, Feb. 18, aged 82.

Rogers, Lincoln, Fallbrook, Calif.; University of Southern California College of Medicine, Los Angeles, 1896; died Jan. 21, aged 91.

Rossomondo, Frank David Ⓜ New York City; Cornell University Medical College, New York City, 1930; member of the American Trudeau Society and the Industrial Medical Association; president of the board of health, Haworth, N. J.; medical director of the McGraw-Hill publications; associate visiting physician of Bellevue Hospital and French Hospital; died in Paramus, N. J., March 7, aged 56.

Schwarz, Gottwald Ⓜ New York City; Medizinische Fakultät der Universität, Vienna, Austria, 1904; honorary member of the American Roentgen Ray Society; served as professor of radiology at the University of Vienna, and director of radiology at the Empress Elizabeth Hospital there; wrote many papers on the aspects of radiological work; died Feb. 26, aged 78.

Schwimmer, Samuel, New York City; Long Island College of Medicine, Brooklyn, 1930; veteran of World War II; served on the courtesy staff of the Beth Israel Hospital, where he died March 3, aged 53.

Scott, Benton Van Dyke Ⓜ Waverly, Ohio; Northwestern University Medical School, Chicago, 1918; veteran of World Wars I and II; retired from the regular Navy on June 30, 1939; health commissioner of Fayette, Pike, and Ross counties, with headquarters in Chillicothe; served as health officer of Hickory, N. C., and Houghton-Keweenaw-Baraga District with headquarters in Houghton, Mich.; died in the U. S. Naval Hospital, Bethesda, Md., Feb. 16, aged 64.

Scott, James Underwood, Harrisonville, Mo.; Missouri Medical College, St. Louis, 1894; associated with the Memorial Hospital, where he died Feb. 3, aged 88.

Shields, John Aloysius Ⓜ Brooklyn; Columbia University College of Physicians and Surgeons, New York City, 1898; associated with St. Mary's Hospital, where he died Dec. 16, aged 81.

Short, Jacob Ⓜ St. Paul; University of Minnesota Medical School, Minneapolis, 1928; veteran of World War II; died in Miami, Fla., Feb. 22, aged 55.

Simpson, Austin Ulysses Ⓜ Seattle; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; retired chief epidemiologist for the state department of health; formerly chief of laboratories for the state department of health, and at one time assistant director; served in France during World War I; formerly associated with the U. S. Public Health Service; died Feb. 6, aged 89.

Sinks, Edward Dimmitt, Lima, Ohio; Medical College of Ohio, Cincinnati, 1899; veteran of the Spanish-American War; served overseas during World War I; on the staffs of the Lima Memorial and St. Rita's hospitals; died in the Veterans Administration Hospital, Dayton, Feb. 1, aged 81.

Snyder, Roscoe Howe Ⓜ Toledo, Ohio; University of Michigan Medical School, Ann Arbor, 1927; member of the American Academy of General Practice; served during World War II; on the staff of St. Vincent's Hospital; died Feb. 21, aged 58.

Stein, David Ⓜ Philadelphia; Jefferson Medical College of Philadelphia, 1924; member of the Industrial Medical Association; on the staff of St. Mary's Hospital; died in the Jefferson Hospital Feb. 25, aged 58.

Stratton, Charles Stewart, Lowry City, Mo.; Barnes Medical College, St. Louis, 1899; died Feb. 3, aged 89.

Teaford, Benjamin Jay, Corydon, Ind.; University of Louisville (Ky.) Medical Department, 1902; veteran of World War I; at one time served as health commissioner of Bartholomew County; died Feb. 23, aged 81.

Tinker, Burgoyne Livingstone, West Middlesex, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1902; veteran of World War I; died in the Sharon (Pa.) General Hospital Feb. 24, aged 80.

Tracey, William Wallace, Norwalk, Conn.; Columbia University College of Physicians and Surgeons, New York City, 1916; died Feb. 14, aged 66.

Unruh, Rudolph Theodore Ⓜ Kinsley, Kan.; University of Kansas School of Medicine, Kansas City, 1930; served as medical missionary in the African Belgian Congo; veteran of World War II; died in the Edwards County Hospital Feb. 20, aged 59.

Van Pelt, Clifford Alexander Jr. Ⓜ Long Beach, Calif.; University of Kansas School of Medicine, Kansas City, Kan., 1937; member of the American Academy of General Practice; vice-president of the General Practice Section, Los Angeles County Medical Association; interned at St. Luke's Hospital in Kansas City, Mo.; veteran of World War II; member of the staffs of the Seaside and St. Mary's hospitals; secretary of the medical staff, Community Hospital, where he died Jan. 27, aged 49.

Vestermark, Seymour Day Ⓜ Medical Director, U. S. Public Health Service, retired, Bethesda, Md.; born in Dixon, Ill., Nov. 25, 1902; State University of Iowa College of Medicine, Iowa City, 1931; specialist certified by the American Board of Psychiatry and Neurology; fellow of the American Psychiatric Association, which last January cited him for his outstanding service to psychiatry; from 1948 to 1958 chief of the training and standards branch of the National Institute of Mental Health; past-president of the Commissioned Officers' Association of the U. S. Public Health Service; died in the U. S. Public Health Service Hospital, Baltimore, Feb. 22, aged 56.

Vinnedge, Kenneth Houston Ⓜ Captain, U. S. Navy, retired, Quincy, Ill.; born in Waterloo, Iowa, April 21, 1901; University of Illinois College of Medicine, Chicago, 1930; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; entered the U. S. Navy in June, 1929; at different times was chief of the department of radiology at Naval hospitals at Great Lakes, Ill., Philadelphia, Brooklyn, Pearl Harbor, Hawaii, Coca Sola, Canal Zone, and Oakland, Calif.; during World War II was first assigned as senior medical officer on the cruiser Columbia at Guadalcanal, later as staff medical officer of the commander of naval forces in the Southwest Pacific, and finally as executive officer of the naval hospital at Guam; when he retired in May, 1953, was executive officer at the Naval Hospital at Great Lakes; died in Daytona Beach, Fla., March 5, aged 57.

Wood, Kavanaugh Payne, Lena, Miss.; Memphis (Tenn.) Hospital Medical College, 1909; on the staff of the Leake County Memorial Hospital in Carthage Jan. 27, aged 78.

Wood, Lawrence Edward Ⓜ Kansas City, Mo.; University of Kansas School of Medicine, Kansas City, Kan., 1926; member of the American College of Chest Physicians and the American Trudeau Society; associate clinical professor of medicine at his alma mater; served as president of the Missouri State Tuberculosis Association and as a member of the board of the National Tuberculosis Association; veteran of World War II; on the staff of the University of Kansas Medical Center in Kansas City, Kan., and St. Luke's Hospital; affiliated with the Veterans Administration Hospital; died Feb. 3, aged 59.

Woods, Limmie Bradford Ⓜ Lubbock, Texas; Southwestern University Medical College, Dallas, 1911; during World War II a lieutenant colonel in the Texas State Guard; formerly city health officer; on the staff of the Methodist Hospital; died Feb. 5, aged 71.

Zimmerman, Victor Leo Ⓜ Chatham Center, N. Y.; Bellevue Hospital Medical College, New York City, 1897; fellow of the American College of Surgeons and the New York Obstetrical Society; past-president of the Brooklyn Gynecological Society; veteran of the Spanish-American War; associated with Brooklyn, St. Mary's and Holy Family hospitals in Brooklyn, and Mary Immaculate Hospital in Jamaica; died in the Columbia Hospital, Hudson, Feb. 3, aged 87.

FOREIGN LETTERS

AUSTRIA

Carcinoma of Skin.—At the meeting of the Society of Physicians in Vienna on Feb. 27, Dr. A. Matras stated that in cork tile factories a mixture of cork chips is cast into tiles by adding heated coal tar pitch. The workmen are constantly exposed to special risks due to the effects of the pitch dust which are particularly severe when further exposed to solar irradiation. In the course of years the exposed skin of the workmen develops a bronze pigmentation and a verrucous hyperkeratosis, which forms the basis for the formation of carcinoma which often occurs only after several decades of exposure and develops particularly in the face, hands, and forearms. In a series of six patients carcinoma of the nose was observed in one after eight years of occupational exposure. In the others carcinoma was observed only after an average exposure of 29 years. In five of the six patients the carcinoma was cured by combined surgical removal and irradiation, but one patient died of a pharyngeal extension of the carcinoma.

Progress in Cerebral Angiography.—At the meeting of the Society of Physicians in Vienna on Feb. 20, Dr. H. Brenner described the attempts to make cerebral angiography a more valuable, simpler, and less dangerous procedure. Simple puncture with a cannula armed with a syringe; injection, without a tube, of 3 to 5 cc. of a mixture of methylglucamine salt and sodium salt of 3, 5-diacethylamino-2,4,6-triiodobenzoic acid (Urografin); and simultaneous serial exposures at selectable intervals with the aid of the Siemen's cranial film transport mechanism proved to be highly advantageous in almost 500 angiographies. General anesthesia is limited to a few indications, and local anesthesia is to be avoided. Further advantages of the method include short exposure time, large focal film distance, and large size of picture. Filming was successful in 99.8% of cases. Complications did not occur despite unfavorable factors presented by some patients.

Thrombosis.—At the meeting of the Austrian Society for Gynecology and Obstetrics in Vienna in February, Dr. H. Leeb reported that thrombosis is prevented in his patients by early ambulation, physical exercise, and massage. Chemoprophylaxis is possible only in patients who are in danger. Venostasin (an extract of horse chestnuts containing vitamin B_1) given intravenously for seven days postoperatively proved to be effective insofar as it reduced the thromboses, in a series of 1,393 patients, to almost half of the expected number. The number of infarctions was not influenced. An increase in the number of cases of thrombosis in the week after termination of treatment suggests that prophylactic doses of Venostasin should be continued until the patient is completely recovered. Panthesine (*p*-aminobenzoyl-N-diethylleucinolmethansulfonate), Hydergine (methanesulfonates of hydrogenated ergotoxic alkaloids), and phenylbutazone were used prophylactically. Early ambulation and physiotherapy were considered the most important prophylactic treatment in the control of venostasis. The physician should be on the lookout for early signs of thrombosis. Should a deep thrombosis occur heparin or phenprocoumon should be given.

Varicose Veins.—At the same meeting Dr. K. Sigg stated that it is possible to cure all varicosities in ambulant patients with injections of sclerosing agents. Varicose ulcers also benefit from this treatment. Sclerosing agents should not be used, however, without compression bandages. They should not be injected into patients while they are standing; the leg should be horizontal. Only small amounts of these agents should be used for each injection. Several such injections, possibly in both legs, can be made in one session. The patient should not be confined to bed when she has a reaction to the sclerosing injection, but should continue treatment with firm compression and continue with her work. Fast palliation if severe pain occurs may be achieved by an injection of phenylbutazone. More than half of all varicose ulcers are the result of a deep thrombosis. All such ulcers can be healed by compression with an elastic bandage, which makes the edema disappear. The patient does not have to be confined to bed.

Good prophylactic treatment of thrombosis may prevent the severe, deep, often fatal thrombosis which may be followed by ulcers and varicosities. Treatment of the superficial thrombosis should never consist of bed rest. Incision of the superficial thrombosis results in sudden subjective and objective improvement. On initial treatment a firm compression bandage is applied. This is covered by an elastic bandage. Within several hours after phenylbutazone was given pain was relieved and the swelling and acute redness disappeared. This enabled the patients who were immobilized by pain

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

to walk again and continue with their work. The deep thromboses should likewise not be treated by bed rest either, except in patients with fracture of the spine or femur or severe systemic disease. Therapy by compression and early ambulation after operations and deliveries combined with the administration of phenylbutazone is important in the prophylactic treatment and constitutes better management than treatment with anticoagulants. Treatment of thrombosis without a compression bandage is inadequate.

Hormonal Cytodiagnosis in Man.—At the same meeting Dr. K. Klein reported having tested the reaction of the male oral mucosa to hormonal stimulation. Cytological and cytometric examinations of 600 oral smears showed that the male oral mucosa, when stimulated by estrogens or androgens, is as a rule subjected to the same laws as the female oral and vaginal epithelium. The sensitivity to hormonal influences, though, is lower than in women. The method is adequate as a morphologic aid in the objectification of disturbances of the sexual hormonal balance in man and their response to therapy.

BRAZIL

Congenital Heart Defects.—Dr. Sylvio Borges and co-workers presented to the Fifth Regional Meeting of the Associação Paulista de Medicina a report on the treatment of 1,000 successive patients with congenital heart defects. They classified their patients as those (1) with a proved diagnosis (326); (2) with clinical findings complemented by electrocardiograms, phonocardiograms, and roentgenograms sufficiently characteristic to establish the diagnosis (321); (3) with a doubtful diagnosis (199); (4) with congenital cyanosis (57); (5) without cyanosis (38); and (6) those difficult to classify (59). A definite diagnosis was made in 647 (the first two groups). The most frequent malformation found was the tetralogy of Fallot, present in 11.2% of patients. The second was the interventricular septal defect (10.7%), followed by the interauricular septal defect (7.9%), patent ductus arteriosus (7.4%), and coarctation of the aorta (2.8%).

Electrocardiography During Artificial Hibernation.—The use of artificial hibernation for cardiovascular operations is increasing every day, but hibernation with circulatory arrest is not without danger. R. Marques Lisboa and co-workers of the Rio de Janeiro Sanatorio Santa Theresa (*Revista brasileira de cirurgia*, vol. 36, 1958) made periodic electrocardiograms of 17 dogs operated on under artificial hibernation with a circulatory arrest of 8 to 10 minutes. They observed that arrhythmia was not present during the induction phase of hibernation. The reduction of the dogs' temperature from 40 to 29 C (104 to 84 F) was responsible for the lessening of the heart rate by an average of 80 beats per minute. During this phase the electrocardiograms frequently showed increase in the duration of the P wave, the P-R interval, the QRS complex, and the QT segment, and modifications in the morphology of the ST-T complex and appearance of the so-called Osborn's waves. The duration of the QT interval showed a striking increase, quite out of proportion to the frequency of the heartbeat. This and the frequent alterations of the morphology of the ST-T complex and the appearance of Osborn's waves suggested the presence of electrolytic disturbances as the main cause of these alterations.

Contrary to the reports of other authors, in no one dog of this series was ventricular fibrillation caused by hypothermia alone. This may have been caused by the fact that the dogs' temperatures never were brought below 26 C (79 F), but the authors observed a marked irritability of the myocardium during handling of the heart by the surgeon, with frequent appearance of ventricular fibrillation; in contradistinction to most reports, however, this fibrillation was reversible by electric shock and massage. This did not occur in only one dog. The occlusion of the circulation during hypothermia was responsible for the appearance of ventricular arrhythmia, in all cases represented by ventricular fibrillation or idioventricular rhythm. Afterwards the QRS complexes became more and more similar to those registered at the beginning of hypothermia, attaining at last a nodal rhythm. In almost every dog the T waves remained negative until awakening. The authors believed that circulatory arrest and ventricular fibrillation cause, in artificially hibernating dogs, an extreme depression of the heart and its conduction system, responsible for the appearance of the idioventricular rhythm. They based their opinion on the marked progressive decrease of the heart rate and the transformation of the QRS complex to more and more abnormal shapes of longer duration in the course of the circulatory arrest.

ICELAND

Poliomyelitis.—Julius Sigurjónsson (*Nord. med.* 61:174-177 [Jan. 29] 1959) stated that poliomyelitis has apparently been endemic in Iceland since 1924 and that extensive epidemics have occurred periodically only once in about 10 years. A marked shift in age selection in the direction of adolescents and adults has been observed in the more recent epidemic years. The shift was considered to be exaggerated, however, as a result of confusion with a simultaneously prevalent poliomyelitis-like disease sometimes called Iceland disease. Of 459 poliomyelitis cases with 89 deaths reported for 1924 148 were in patients under 4, 185 in those between 5 and 14, and the rest in patients between

15 and 60 years of age. Of 300 cases with 29 deaths reported for 1935 75 were in patients under 4 and 110 were in patients between 5 and 14 years of age. The trend started to change in 1945 with 368 cases and 10 deaths, with 52 in patients under 4 years of age, 110 in the 5-to-14-year-old group, and 113 cases for the 20-to-39-year-old group. In 1946-1947 there were 671 cases with 18 deaths and in 1955-1956 1,154 cases with 3 deaths.

INDIA

Aortic Regurgitation.—V. G. Joshi (*Journal of the Association of Physicians of India*, vol. 7, January, 1959) reviewed a series of 39 patients (32 men and 7 women) who had aortic regurgitation. Of these 25 came to hospital as medical emergencies, with signs and symptoms suggestive of cardiac failure. Only three were asymptomatic. The age at onset of symptoms varied from 15 to 70 years. Although the disease in the earlier age group was predominantly rheumatic in origin and in the later age group syphilitic in origin, this was not always true. Thus one patient with syphilitic aortic lesions came to hospital with signs of heart failure before the age of 25 years while another with a definite history of rheumatic fever and combined mitral and aortic lesions was admitted for heart failure at the age of 40. The interval between primary infection and onset of symptoms in the syphilitic group varied from about 5 to 20 years. The corroborations of syphilis by history and by positive serologic tests were not always correlated. Tertiary cardiovascular syphilis in the form of aortic regurgitation occurred within two years of primary infection in two patients before the age of 25.

Eleven patients complained of precordial or epigastric pains. In one this was due to an enlarged tender liver, in another to hypercyanotic angina, and in the rest to coronary insufficiency. Angina was thus noticed to be an early and important symptom of aortic regurgitation. Only two patients complained of an anginal syndrome before the onset of dyspnea. Three had palpitations and one of these had an irregular rhythm with extrasystoles. Three gave a history of fever and in one this was probably due to subacute bacterial endocarditis. Thirty showed enlargement of the heart.

The first mitral sound was accentuated in eight and weak or partially replaced in three patients. In seven the second aortic sound was normal and in another seven feeble or absent. It was split in one patient. The second pulmonary sound was accentuated in eight and weak in five. An accentuated first mitral sound always indicated concomitant mitral stenosis or left ventricular hypertrophy. A weak or absent second aortic sound was not a constant finding and not diagnostic of aortic regurgitation; but in no case, even with systolic hypertension, was the aortic second sound accentuated. An accentuated pulmonary second sound meant associated mitral disease. A diastolic thrill was palpable at the apex in five patients and a systolic in three. A diastolic thrill at the base was present in two and a systolic in two. A diastolic murmur at the base was heard in 38 and could be described variously as soft, blowing, harsh, musical, early, and to-and-fro. The murmur was heard best on the left side of the sternum in the third and fourth interspace in 22 patients and also equally on the right side of the sternum either alone or in combination with the above in 23.

An associated diastolic thrill was noticed in two. In one it was associated with a diastolic thrill at the apex and in another with a systolic thrill at the base. A systolic thrill over the base was felt in three and indicated associated aortic stenosis. In five patients with a diastolic thrill at the apex there was an associated mitral stenosis, while in two a systolic thrill at the mitral area indicated mitral regurgitation. A combination of systolic and diastolic elements of a to-and-fro murmur heard diffusely over the precordium, the diastolic element of which was heard best to the left of the sternum, was the most frequent auscultatory finding in this series. In four patients with congestive heart failure a diastolic murmur at the base was either missed or absent at the first examination but became apparent when the failure partially resolved after treatment.

Twenty-nine patients had a Corrigan pulse and 33 showed increased pulse pressure. The systolic blood pressure was more than 160 mm. Hg in 12 patients and the diastolic more than 100 mm. Hg in 2. Increased pulse pressure was a more reliable sign than a Corrigan pulse. Four patients had severe and 15 had moderate anemia. The serologic tests for syphilis were strongly positive in 26 patients and doubtful in 2. Radiologically, enlargement of the heart was present in 21 patients, the left ventricle being mainly affected. Seventeen showed diffuse dilatation of the aorta and nine had an enlarged left auricle. The electrocardiogram showed evidence of left ventricular hypertrophy or strain in 21 patients, combined left and right ventricular hypertrophy or strain in 3, and myocardial damage in 16. Thus more patients showed myocardial damage and coronary insufficiency on electrocardiographic examination than clinically.

Causes of Tooth Loss.—F. S. Mehta and co-workers (*Journal of the All-India Dental Association*, vol. 30, December, 1958) analyzed the nature of 11,830 teeth requiring extraction in 4,278 patients. The primary causes of extraction included (1) caries, (2) periodontal disease, (3) impactions, (4) facilitation of better prosthetic restoration, (5) correction or prevention of malocclusion, (6) supernumerary teeth, (7) trauma, and (8) alveolar abscess. Periodontal disease accounted for 66.3% of the teeth lost and caries for 26.7%. Impactions accounted for only 0.5% and supernumerary teeth for about 0.1%. Extractions due to caries were significantly higher among women than men. The largest number of extractions was in persons 41 to 50 years of age. Extractions due to caries were more frequent in the younger age group (11 to 30) as compared to periodontal disease, while the reverse was true in the older age group. The average number of extractions was maximal in periodontal disease, being 6.24 per patient, while caries accounted for 2.32 teeth per patient. In almost all diseases, the average number of extractions per person was more in women than in men. The number of extractions per patient for prosthetic reasons was high. The average number of extractions per patient increased with increasing age.

UNITED KINGDOM

Artificial Kidney for Streptomycin Poisoning.—It is well known that streptomycin can cause vestibular damage and deafness and that this is more likely to occur in patients with defective renal function. The fact that the drug is normally eliminated from the body by glomerular filtration suggests the possibility that it may be removed in an emergency by extracorporeal hemodialysis. Tests carried out by Edwards and Whyte showed that this is possible, and they now regard the administration of streptomycin in an oliguric patient as a clear indication for early treatment with the artificial kidney (*Brit. M. J.* 1:752, 1959). A simple semiquantitative test showed that streptomycin could be dialyzed from blood across the same cellulose membrane as is used in the artificial kidney. From 40 to 100% of an added quantity of streptomycin diffused across the membrane in 18 hours. Five oliguric patients receiving a dose of more than 1 Gm. of streptomycin were treated by hemodialysis for varying periods. No sign of streptomycin toxicity developed. The authors emphasized the importance of estimating renal function before giving a course of streptomycin.

Hazards of Subway Travel.—At a meeting of the Royal Society of Health Dr. L. G. Norman, the London Transport Executive's chief medical officer, discussed the possibility of banning smoking on London's subway. He thought that public opinion would gradually turn against smoking in public places until no smoking would be permitted in the subway. The London Transport Executive has set up an operational research team to investigate the desirability of increasing the nonsmoking accommodations from 30 to 50% of the total. Dr. Norman said that a taciturn Englishman does not spread infection as readily as his more voluble neighbor. Not talking in trains helps to keep down infection, particularly when large numbers of people stand with mouths and noses in close proximity. The closed mouth minimizes the spread of infection. Dr. Norman also suggested that a few minutes' travel in a train or public vehicle close to an infective neighbor who literally keeps his mouth shut may produce some degree of immunity, as only a small inoculating dose of organisms passes from the infected person to the other.

Inquiry into Drug Prices.—Inquiries into the prices of standard drugs and proprietary preparations were prompted by complaints by the Committee of Public Accounts that pharmacists were enjoying unintended profits on National Health Service drug prescriptions. This was disclosed by the treasury in a comment on the committee's reports. The committee recommended some immediate general reduction in the drug tariff. The treasury now reports that, since March, 1958, the Ministry of Health has made reductions in the reimbursement rates which are estimated to produce savings totaling about $1,064,000 per year. It agrees that so long as the prices actually paid by pharmacists for drugs are not known there can be no assurance that their remuneration is no more than is fair or reasonable. Proposals for further inquiries into the actual cost of drugs are being discussed with the druggists.

Rubella and Pregnancy.—Dr. Julia Bell collected data on the outcome of 712 pregnancies in women who had rubella during pregnancy (*Brit. M. J.* 1:686, 1959). In 694 cases the infection occurred within the first 16 weeks, and in the rest the time of onset was unknown. Information was obtained from hospitals in which the children were born, from questionnaires sent to parents of children just starting school, and from special hospitals for the deaf, the blind, and cardiac cripples. The 712 pregnancies resulted in 421 defects, some children having more than one defect. Cataract was noted in 491 cases (69%), deafness in 263 (37%), and congenital heart disease in 210 (30%). In addition, 70 children were found to show defects other than the three characteristic ones. Many of these defects were not present at 2 years of age but were noted at 6 years or later. The peak incidence of all congenital defects was in children whose mothers had rubella between the fifth and eighth week of pregnancy. This accounted for 35% of the total. The next peak occurred between the 9th and 12th week of pregnancy, during which 100 children, or 24%, were affected. The author believed that abortion should be performed in all cases in which rubella occurs within the first 12 weeks of pregnancy. After that the chances of defects in the offspring are about one in eight.

CORRESPONDENCE

WHIPLASH INJURIES

To the Editor:—I have read the paper on whiplash injuries by Dr. Emil Seletz in The Journal, Nov. 29, 1959, and must take issue with many statements therein. The statement is made that "The disturbance of the great occipital nerve is further aggravated by spasm of the trapezius muscle, since traction is thereby exerted on the nerve as it pierces the tendinous attachment of the muscles to the base of the skull." I seriously doubt that spasm of the trapezius muscle is capable of producing traction on the second cervical nerve and would welcome an explanation as to the mechanism of traction on this nerve by spasm of the trapezius.

Dr. Seletz further said, "Please remove the term (whiplash injury) from your wastebasket to a place of prominence on your mahogany desk." Dr. Seletz' orthopedic friend, to whom this statement was directed, probably does not take objection to the term "whiplash" per se but rather feels that it is no more descriptive than the statement that a patient "turned his ankle" in describing a sprain of the ankle joint. Whiplash injury denotes no specific pathological or anatomic derangement, and the term, therefore, has fallen into disrepute. The patient has sustained a strain of the cervical spine, or a fracture, or a dislocation. The mechanism of injury may have been on a whiplash basis, but the pathological fiindings are not a whiplash injury.

Dr. Seletz further stated that, "In addition, the disk portions are even smaller in their relative sizes, because on either side the space is occupied by special synovial joints not present in other parts of the spine. Although described in 1858 by Von Luschka, they are rarely given proper attention because of the misleading diminutive proportion, but the role played by them is most significant." Furthermore, though Dr. Seletz stated that the role of these joints is more significant, he did not elaborate on this. To my knowledge these joints are of relatively little significance, and there is further question that they are actually joints.

Again I quote, "With degenerative thinning of the disk after trauma, the processes of the lateral joints are gradually forced outward and laterally, resulting in osteophyte formation." I doubt that the processes of the lateral joints are forced in any direction. Certainly osteophyte formation may occur as a result of proliferation at ligamentus attachments. I also doubt that the lateral joints are actually "forced out."

Another quotation is "If the blood vessel wall has been traumatized during the injury or the vertebral nerve has been injured, vasospasm persists. The only true, effective measures for tiding over this stage of injury lie in adequate physical therapy." This statement is much too sweeping in its scope, and certainly vascular surgeons and those familiar with the treatment of vasospasm believe that there are multiple adjunctive measures other than "adequate physical therapy" to relieve vasospasm.

Dr. Seletz' statements relative to traction without clarification of the uses and abuses of traction are much too sweeping and are in direct opposition to his earlier statements relative to traction on the second cervical nerve produced by "spasm of the trapezius."

I further would question the following statement: "I personally resent the extensive use of the so-called tranquilizing drugs in this type of case, the sole purpose of which is to confuse the mind so that the patient will not complain." I doubt that any physician has ever prescribed a tranquilizing drug for the purpose of confusing the patient's mind so that the patient no longer complains.

WHAT IS AN INTERNIST?

To the Editor:—There seems to be increasing interest in defining, in a concise manner, the functions of an internist. Probably because internal medicine is such a broad field, it is easier for the public to think of an internist in terms of what other specialists are not. This leads to the confusing of internists with general practitioners and interns.

In an effort to find a positive, concise definition of an internist, we are publishing in the Program of the 49th Annual Session of the American College of Physicians held in Chicago, April 20-24, 1959, the following suggested definition: "An internist is a physician trained as a specialist in the diagnosis and medical treatment of internal diseases in the adult." We shall welcome criticisms, comments, and improvements on this definition.

MEDICAL LITERATURE ABSTRACTS

THERAPEUTICS

Acute Granulocytic Leukemia in Pregnancy: Report of Four Cases with Apparent Acceleration by Prednisone in One. H. Rothberg, M. E. Conrad and R. G. Cowley. Am. J. M. Sc. 237:194-204 (Feb.) 1959 [Philadelphia].

Acute granulocytic leukemia was observed in 4 pregnant women, between the ages of 15 and 35 years. Although in a recent comprehensive review of the subject it was maintained that corticosteroids should be preferred to any of the antimetabolites for the treatment of acute leukemia during pregnancy, these 4 cases show that corticosteroids also may have their drawbacks in the therapy of this disease in the pregnant patient. The first of the 4 pregnant women did not receive specific treatment for her acute leukemia; she was delivered spontaneously of a macerated fetus, whose death was attributed to premature separation of the placenta; the mother died 2 days after the delivery. The second woman conceived while being treated with mercaptopurine for her granulocytic leukemia; despite this fact and the prolonged use of mercaptopurine and cortisone, and, in addition, of aminopterin sodium and a trial of desacetylmethylcolchicine (Demecolcin), she was delivered spontaneously of a premature infant, which was free of any malformation, and died 5 days after the delivery. Although the simultaneous use of several drugs made it impossible to attribute either of the 2 remissions in this case to any one agent with certainty, it was clear that cortisone was at least not harmful to the patient and was probably beneficial.

In the third patient the administration of prednisone was associated with a dramatic acceleration of the leukemic process, manifested by a rapid rise in the leukocyte count and severe bone pain. Although the mechanism remains obscure, the case of this patient added to the increasing accumulation of clinical evidence that steroid hormones may aggravate certain cases of acute granulocytic leukemia. Because of this unfavorable experience with steroid therapy, the fourth patient was treated with mercaptopurine only; this drug was given during the last 4 months of pregnancy. The patient bore her pregnancy well and had a full-term normal delivery. There was no evidence of any deleterious effect of the mercaptopurine on the fetus. The only evidence of drug toxicity in the mother was a marked leukopenia during the initial phase of therapy, associated with an acute febrile attack; this was controlled by withdrawal of the mercaptopurine and institution of antibiotic therapy.

The limited life expectancy of the patient with acute leukemia makes it highly unlikely that she can sustain a normal pregnancy. Fetal salvage is low irrespective of treatment. There is no evidence of transplacental transmission of leukemia. In the management of acute leukemia in pregnant women, steroids are not necessarily superior to antimetabolites. The best over-all therapeutic regimen is that which is most effective against the leukemia itself.

Reserpine, Gastric Secretion, and Peptic Ulcer. W. H. Bachrach. Am. J. Digest. Dis. 4:117-124 (Feb.) 1959 [New York].

The author made clinical and laboratory observations on private patients and on patients in the neuropsychiatric hospital of the Veterans Administration Center in Los Angeles, who had been treated with reserpine for hypertension or for psychotherapeutic sedation, as well as on patients treated for peptic ulcers in the gastroenterology section of the Wadsworth Hospital of the V. A. Center. Neither these data nor a review of the literature yielded any convincing evidence that reserpine is an important ulcerogenic agent. Single, orally administered doses of reserpine (0.25 to 0.5 mg.), such as are used in the management of hypertension, stimulate the secretion of hydrochloric acid by the stomach only mildly; this effect may be prevented by the simultaneous administration of a therapeutic dose of an anticholinergic drug. Prolonged therapy with reserpine in these doses does not lead to gastric hypersecretion. Single large doses of reserpine (1 mg. or more), given orally or parenterally, usually provoke an intense and sustained secretion of hydrochloric acid, which is not prevented by even large doses of anticholinergics. The cumulative effects of these large doses are unknown. Large doses of reserpine are

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

used in psychotic patients, who should, therefore, be screened for the presence of ulcer before and at intervals during treatment. Reserpine in large doses should be used with caution, or not at all, in patients with ulcer, but the reported data do not indicate that this constitutes an important problem in the over-all applicability of the drug.

Induction of Acute Gastric Lesions by Histamine Liberators in Rats: Effects Thereon of Pharmacologic Blocking Agents. S. Franco-Browder, G. M. Masson and A. C. Corcoran. J. Allergy 30:1-10 (Jan.-Feb.) 1959 [St. Louis].

The authors report on experiments performed on rats to demonstrate the nature of gastric lesions evoked by a potent histamine liberator, polymyxin B, and to attempt an analysis of their mechanism by administration of drugs which are known to block some of the pharmacological effects of naturally occurring amines. Three groups of 12 animals each received treatment, consisting of a single intraperitoneal injection of polymyxin B in doses of 2.0, 1.0, and 0.5 mg. per kilogram of body weight respectively. Within minutes after the injection the animals were in shock, prostrate, cyanotic, and dyspneic. Seven hours later 6 animals from each group were killed, and autopsy was performed. Large, dark, purplish areas, located exclusively in the glandular part of the stomach, were visible through the serous surface. Besides these lesions, hemorrhagic ulcerations were seen in part of the cecum.The glandular mucosa of the stomach showed hemorrhagic erosions which polymyxin B had caused in all the animals, but the effects of the substance were less in those given the smaller doses, the incidence and severity of the lesions decreasing sharply in those given only 0.5 mg. The remaining 6 animals of each group were killed from 1 to 4 days after the injection of polymxyin B. Autopsy revealed that healing of the stomach walls had begun immediately and that epithelization may be complete in 4 days.

The effects of pharmacological blocking agents on the production of gastric lesions were next studied in 80 polymyxin-treated rats. Results in terms of gastric ulceration showed that only the antihistamines and phenoxybenzamine hydrochloride (Dibenzyline), an adrenolytic compound which also possesses antihistaminic properties, afforded protection from the ulcer-inducing properties of polymxyin B. In order of effectiveness the antihistamines were promethazine (Phenergan), chlorpheniramine (Chlor-Trimeton), phenindamine (Thephorin), and parabromdylamine (Dimetane). Phenoxybenzamine was as active as promethazine in protecting against erosions, but two other blocking agents, lysergic acid diethylamide (LSD) and chlorpromazine, had no significant effect on the incidence and severity of gastric ulcerations.

The authors studied the modification of the toxic effects of polymyxin B in 8 rats pretreated with reserpine or dextran. Reserpine in dosage of 3 mg. per kilogram of body weight had been given 48 hours before the injection of polymyxin B to 12 animals in one group and dextran in dosage of 300 mg. per kilogram had been given 24 hours before polymyxin injection to 6 animals in another group. Of the controls, 12 animals received polymyxin B alone, 12 received reserpine alone, and 6 received dextran alone. Polymyxin B elicited shock and death in one-half of the animals in the first group; reserpine provoked drowsiness, piloerection, salivary hypersecretion, and defecation in the animals in the second group; dextran caused only hyperemia and edema of the nose and extremities in the animals in the third group. When polymyxin B was given to rats pretreated with reserpine, shock did not occur, and the extremities were hyperemic rather than cyanotic. Symptoms usually caused by polymyxin B were alleviated in those rats pretreated with dextran; shock did not occur, and only some of the animals experienced moderate dyspnea and cyanosis. Examination of the stomach showed that dextran was the only agent that had not caused gastric lesions, reserpine had provoked the formation of punctiform erosions, but these were insignificant as compared with those evoked by polymyxin B. Reserpine had no effect on the gastric lesions induced in rats that 2 days later received polymyxin B, whereas a prior administration of dextran reduced the severity but not the incidence of the erosions.

These experiments show that the toxic effects of polymyxin B may be modified by other amine liberators and its ulcer-inducing properties may be suppressed by adequate dosages of antihistaminic and adrenolytic agents. The method described provides a new technique for the production of gastric ulcers and for study of their healing.

PATHOLOGY

Benign Thymoma and Selective Erythroid Aplasia of the Bone Marrow. E. M. Jacobs, R. V. P. Hutter, J. L. Pool and A. B. Ley. Cancer 12:47-57 (Jan.-Feb.) 1959 [Philadelphia].

The association of anerythroid anemia and benign thymoma has recently emerged as a clinical and pathological entity. The recognition of this association is of particular interest because of the occasional complete remissions of the anemia after thymectomy. During 1957, 2 patients at Memorial Center for Cancer and Allied Diseases, New York, were found to have this syndrome. Their histories are presented. The first patient, a 58-year-old man, had a thymoma that was benign, or at worst locally malignant, for 18 years before severe anemia developed, which was associated with selective aplasia of the erythroid precursors in the bone marrow. This man also had mild thrombocythemia of an obscure nature. His death was caused by viral hepatitis presumably resulting from blood transfusions. The second patient, a 64-year-old woman, presented with both a large benign thymoma and anerythroid anemia. In this patient removal of the thymic tumor was followed by complete hematological remission.

Five cases of thymoma with coexisting anemia were reported from 1928 to 1953. Since 1953 an additional 21 cases, including the 2 cases recorded here, have been reported. The clinical features of these 26 patients are analyzed. In 17 of the patients there was a virtual absence of reticulocytes in the peripheral blood and a selective aplasia of the erythroid precursors in the marrow without any other hematological abnormality. The remaining 9 patients had other hematological abnormalities, but the essential change in the bone marrow of 5 of these patients was absence of the erythroid series. Five of the 26 patients had myasthenia gravis in addition to the thymoma.

Since a causal relationship between benign thymic tumors and erythroid aplasia was suggested in previous reports, all cases of thymic tumor in adults seen at Memorial Center for Cancer and Allied Diseases since 1926 were reviewed. There was a total of 30 thymomas with pathological confirmation; 14 were true thymomas, and the others were malignant thymomas of the seminomatous type. Of the 14 patients with benign thymoma, the 2 described here were the only ones who had any degree of anemia. The incidence of myasthenia gravis among these 14 patients was the same. None of 16 patients with malignant thymoma had either this kind of anemia or myasthenia gravis.

Of 46 cases of selective erythroid aplasia reported in the literature, 26 (or 52%) of the patients had an associated benign thymoma. Of 16 patients with this syndrome who underwent thymectomy, 4 patients (including the second one mentioned above) obtained a complete hematological remission, and an additional 3 patients showed definite but incomplete improvement in the anemia. No histological criteria could be defined which were unique to thymomas associated with anerythroid anemia. The authors conclude that benign thymomas are associated with anerythroid anemia with approximately the same frequency as with myasthenia gravis. Therefore, any patient with benign thymoma should be kept under continuous hematological control. Since about half of the adult patients with anerythroid anemia have an associated benign thymoma, search for such a tumor is strongly indicated in any patient who presents this type of anemia. Although thymectomy only occasionally and unpredictably induces hematological remissions, it is the only effective procedure available. The pathogenetic mechanisms relating benign thymoma to anerythroid anemia remain obscure.

Hemangiopericytoma of Stout and Murray. F. Coste, J. Uro and J. Guilaine. Presse méd. 66:2029-2030 (Dec. 25) 1958 (In French) [Paris].

Hemangiopericytoma presents prognostic difficulty, because histological findings may suggest a benign lesion, whereas the medical observation reveals malignancy. It seems that the location of the primary lesion is decisive for the prognosis. The authors report a patient, 51 years of age, in whom a painless and apparently benign tumor, the size of a walnut, appeared on the upper margin of the right popliteal fossa in 1930 and had been quiescent for 20 years. The tumor began to expand in 1950, so that the circumference of the right thigh had been gradually increasing, but without accompaniment of pain. After 6 years of gradual growth on the part of the thigh tumor, pain appeared in the right side of the sacroiliac region, followed after a few months by the appearance of a tumor in the posterior iliac region. The new tumor had the same characteristics, but its growth progressed faster than that of the primary lesion. Roentgenologic examination in July, 1957, revealed osteolysis on the right side of the ilium. The pain grew worse, evolving into sciatic neuralgia a month later.

The tumor in the right thigh was voluminous and appeared to be a sarcoma at the time of the patient's admission. There was a marked venation under the skin of the tumor, and a slightly elevated local temperature. The tumor was not hard in consistency; several nodes were palpated under its skin, mostly in the region of the popliteal fossa. A murmur synchronous with the pulse was auscultated in the thigh. No abnormality of the adjacent lymph nodes was noted. A longitudinal band of indurated tissue, 5 to 6 cm. in length, was palpated in the anterior side of the thigh.

The tumor in the iliac region had features similar to those of the tumor in the thigh, including venation under the skin and a distinct pulsation. Roentgenologic examination revealed the band of indurated tissue under the skin of the thigh tumor and a considerable osteolysis on the right side of the ilium and of the sacroiliac joint, but the bones of the right leg were normal. Specimens of the thigh induration and of the tumor in the popliteal fossa were obtained by biopsy. The microscopic examination revealed that the induration in the anterior side of the thigh was an osteoma unrelated to the tumor in the popliteal fossa. The latter tumor was a whitish mass, well encapsuled, with surface venation, which was diagnosed as a nonmalignant hemangiopericytoma. This case demonstrates the incidence of a clinically malignant hemangiopericytoma, which malignancy could not be confirmed by histological findings.

The Use of Selective Media for the Detection of Beta-Haemolytic Streptococci. W. Brumfitt and P. L. Masters. J. Roy. Army M. Corps 105:38-41 (Jan.) 1959 [London].

The isolation of beta-hemolytic streptococci from the throats of healthy carriers and convalescent patients is difficult. Several techniques have been devised to improve the yield of streptococci. Because the authors were examining large numbers of throat swabs, they decided to compare some of these methods. Swabs from 2,000 soldiers not having sore throats were cultured on blood agar, aerobically (method 1), anaerobically (method 2), and aerobically with the addition of crystal violet to the medium (method 3). Swabs from 520 healthy children and adults were plated on blood agar aerobically (method 1), on crystal violet blood agar aerobically (method 3), and after preliminary incubation in an enrichment medium on a selective medium (method 4). Culture on blood agar incubated anaerobically was efficient and gave better results than aerobic incubation. The use of crystal violet blood agar did not significantly increase the yield of streptococci from carriers. Primary culture in sodium azide, crystal violet, blood agar enrichment medium, followed by subculture onto streptomycin and crystal violet blood agar, gave excellent results, but it is rather cumbersome for routine use.

The Lymphomata of the Gastrointestinal Tract. C. J. Uys. South African J. Lab. & Clin. Med. 4:235-248 (Dec.) 1958 [Cape Town].

The author uses the term "lymphoma" in a generic sense to embrace all neoplasms of lymphoid and reticuloendothelial origin. This group of neoplasms includes 2 benign lesions, namely, benign lymphoma of the rectum and giant follicular lymphoma; it also includes the following 4 malignant lesions: reticulum-cell sarcoma, lymphosarcoma, Hodgkin's disease, and plasmacytoma. The records of the pathology department of the University of Cape Town were searched for cases of lymphoma in which the primary lesion was in the gastrointestinal tract. Over the 6-year period from 1952 to 1957, inclusive, 21 primary gastrointestinal lymphomas were recorded, and 18 of these were classified as malignant. These 18 constituted 2.2% of 811 malignant tumors of the gastrointestinal tract seen during that period. Striking variations in localization were apparent. Lymphomas were commonest in the stomach and in the small intestine, but while the incidence of gastric lymphoma relative to other malignancies of the stomach was 2.5%, which is near the over-all figure, in the small intestine they constituted 41.2%. The esophagus, colon, and rectum, where carcinoma is common, are involved to negligible degree by lymphoma.

The presenting clinical features did not differ significantly from those of carcinoma of the same site. In the stomach, irrespective of microscopic appearances, ulcerative, polypoid, and infiltrating macroscopic types were observed; of these the ulcerative variety was commonest. In the intestine the neoplasms were either polypoid or diffusely infiltrating, and both types predisposed to intussusception. Histologically, 9 were classified as reticulum-cell sarcoma, 7 as lymphosarcoma, 1 as Hodgkin's disease, 1 as plasmacytoma, and 3 as benign lymphoma of the rectum. Attention is drawn to the entity "benign lymphoma of the rectum," which on gross appearance is indistinguishable from rectal polyp but which, histologically, may present diagnostic difficulties. Of the 14 patients followed up, only 6 have survived. One patient, alive 3 years after the operation, represents the longest survival. Excluding the benign form, mortality could not be correlated with any histological type, but 5 of the 8 patients who died showed involvement of the regional lymph nodes at the time of operation.

Studies on Bile Pigment in Bile: II. Clinical Considerations on the Bilirubin Content of Bile in Patients with Various Biliary Tract Diseases. T. Sato. Tohoku J. Exper. Med. 68:293-301 (Oct. 25) 1958 (In English) [Sendai, Japan].

While his associates at the surgical clinic, School of Medicine, Hirosaki University, studied the physical and chemical properties of bile during pathological states, the author investigated the bilirubin content in the bile of patients with various disorders of the biliary tract. His studies were made on 49 patients undergoing laparotomy: 11 patients with gallstones (8 with pigment stones and 3 with cholesterol stones), 5 patients with cholecystitis in the absence of stones, and 7 patients with ascariasis of the biliary tract; the remaining 26 patients were free from biliary tract disease and served as controls. The bile samples were obtained by puncture of the gallbladder during operation. The bile in the common duct was studied in 8 patients: 5 with gallstones, 2 with cholecystitis but without gallstones, and 1 with ascariasis of the biliary tract.

The total bilirubin content in the gallbladder bile of the 26 patients without biliary tract disease ranged from 85.5 to 1,890 mg. per 100 cc., its mean value being 799 mg. per 100 cc. Comparing these values with those of investigators who studied Caucasian subjects, the author concludes that the mean bilirubin content of the gallbladder bile of Japanese subjects is lower than that of Caucasians. The mean total bilirubin values in gallbladder bile of Japanese patients with diseases of the biliary aplasia of the erythroid precursors in the bone marrow. This man also had mild thrombocythemia of an obscure nature. His death was caused by viral hepatitis presumably resulting from blood transfusions. The second patient, a 64-year-old woman, presented with both a large benign thymoma and anerythroid anemia. In this patient removal of the thymic tumor was followed by complete hematological remission.

Five cases of thymoma with coexisting anemia were reported from 1928 to 1953. Since 1953 an additional 21 cases, including the 2 cases recorded here, have been reported. Studies on Bile Pigment in Bile: II. Clinical Considerations on the Bilirubin Content of Bile in Patients with Various Biliary Tract Diseases. T. Sato. Tohoku J. Exper. Med. 68:293-301 (Oct. 25) 1958 (In English) [Sendai, Japan].

While his associates at the surgical clinic, School of Medicine, Hirosaki University, studied the physical and chemical properties of bile during pathological states, the author investigated the bilirubin content in the bile of patients with various disorders of the biliary tract. His studies were made on 49 patients undergoing laparotomy: 11 patients with gallstones (8 with pigment stones and 3 with cholesterol stones), 5 patients with cholecystitis in the absence of stones, and 7 patients with ascariasis of the biliary tract; the remaining 26 patients were free from biliary tract disease and served as controls. The bile samples were obtained by puncture of the gallbladder during operation. The bile in the common duct was studied in 8 patients: 5 with gallstones, 2 with cholecystitis but without gallstones, and 1 with ascariasis of the biliary tract.

The total bilirubin content in the gallbladder bile of the 26 patients without biliary tract disease ranged from 85.5 to 1,890 mg. per 100 cc., its mean value being 799 mg. per 100 cc. Comparing these values with those of investigators who studied Caucasian subjects, the author concludes that the mean bilirubin content of the gallbladder bile of Japanese subjects is lower than that of Caucasians. The mean total bilirubin values in gallbladder bile of Japanese patients with diseases of the biliary tract were 33.8 mg. per 100 cc. in those with pigment stones, 131 mg. per 100 cc. in those with cholesterol stones, 84.8 mg. per 100 cc. in those with cholecystitis without gallstones, and 130.4 mg. per 100 cc. in those with ascariasis of the biliary tract. The bilirubin content in the common duct bile also decreased, the mean value being 72.2 mg. per 100 cc. Thus, the studies revealed that the bilirubin content of the gallbladder bile as well as the common duct bile was reduced during diseases of the biliary tract, and this trend was especially pronounced in patients with pigment stones. The author investigated not only the total bilirubin values but also the conjugated form and the free form, and the ratio of the conjugated to the total bilirubin content. He found that the conjugated form accounts for nearly 90% of the total bilirubin content of the bile, even in biliary tract diseases.

Serum Cholinesterase in Liver Disease. P. N. Wahi, S. Ramachandran and H. Navani. Indian J. M. Res. 47:13-19 (Jan.) 1959 [Kasauli, India].

The depression of the serum cholinesterase activity during the active phase of acute liver disease and its rise upon recovery have been reported by a number of investigators. It has been claimed that serial studies of this enzyme reflect the changing status of hepatocellular function in such patients better than do the other liver function tests. The present study was undertaken to determine the relative sensitivity of the serum cholinesterase test in comparison with 7 other liver function tests in patients with portal cirrhosis and infectious hepatitis. The following liver function tests were performed simultaneously: (1) thymol turbidity, (2) thymol flocculation, (3) zinc sulfate turbidity, (4) colloidal gold flocculation, (5) prothrombin concentration, (6) serum bilirubin, and (7) serum total proteins and albumin. The tests were made on 30 patients with portal cirrhosis, on 24 patients with infectious hepatitis, and on 30 healthy persons (hospital personnel and blood donors). Serum cholinesterase activity was diminished in all the patients with portal cirrhosis; that is, the serum cholinesterase tests proved far more sensitive than the other tests in indicating functional damage to the liver. In infectious hepatitis, however, the serum bilirubin test gave the highest percentage of positive results, while the determination of the serum cholinesterase proved to be no more sensitive than the turbidity and flocculation tests.

The studies also revealed a close relationship between serum cholinesterase and the serum albumin/globulin ratio, but no such relationship was found between the serum cholinesterase and the serum albumin itself. In some of the patients with infectious hepatitis low values of serum cholinesterase were found even when the serum albumin level was normal but the jaundice severe. This contradicts the observations of other investigators. Some other liver function tests, such as the prothrombin concentration and the colloidal gold flocculation, proved highly insensitive as indicators of functional liver damage and, as a result, are of little clinical value. The serum cholinesterase determination remains the best test for ascertaining mild degrees of functional impairment, at least in portal cirrhosis.

RADIOLOGY

Thromboembolism of the Lungs. J. Arendt and M. Rosenberg. Am. J. Roentgenol. 81:245-254 (Feb.) 1959 [Springfield, Ill.].

Based on roentgenologic findings in patients with thromboembolism of the lungs, examined in the radiologic department of Mount Sinai Hospital, Chicago, the authors emphasize that the incidence of this thromboembolism of either surgical or medical origin has remained high despite greater clinical awareness and better methods of prevention, vein ligation, and anticoagulant treatment. The clinical signs and symptoms are frequently suggestive. Roentgenography or angiocardiography is in a high percentage of cases decisive. Thromboembolism without infarction presents as an abnormal transparency of the involved lung segment (Westermark), with absence of one or both of the large hilar vessels. The heart shadow assumes a peculiar shape, best described as the "amphoric" type (resembling a Greek urn). In the absence of both hilar vessels (pulmonary arteries), a large saddle embolus must be considered.

A thrombus or embolus which is located slightly more peripherally within the main branches of the pulmonary arteries causes a buckling and aneurysmal widening of the vessel, with either a sharp cut-off or tapering at the peripheral end of the embolus. Such thrombus or embolus is compatible with life and leads to the development of either acute or chronic cor pulmonale. In contrast to the cor pulmonale of obstructive emphysema, the position of the diaphragm is elevated, the heart does not assume the vertical position, and within a short time enlargement of inflow and outflow tracts of the right ventricle develops.

Patients with thromboembolism leading to infarction do not, as a rule, present Westermark's sign of increased translucency of a lung segment, since it occurs mostly in a congested lung with dilated bronchial arteries and numerous collaterals. Infarction is common in patients with mitral stenosis, hypertensive heart failure, and coronary insufficiency. Infarcts represent an area of ischemic necrosis usually located at the periphery of the lung. They are rarely "wedge-shaped," as the apex of the wedge is cut off. A "truncated cone" or an "umbrella" shape results, which is quite characteristic. Smaller infarcts frequently have a cuboid or meniscus-like appearance. In the costophrenic angle the "hump-shaped" elevation on the medial side of a small pleurisy has frequently been observed and appears diagnostic. The base of the embolic infarcts is sometimes the interlobar fissure line, along which they form a parabolic shadow, which is best seen on a lateral roentgenogram.

The Importance of Chest Roentgenography in the Diagnosis of Pulmonary Embolism. G. N. Stein, J. T. Chen, F. Goldstein and others. Am. J. Roentgenol. 81:255-263 (Feb.) 1959 [Springfield, Ill.].

The authors report on 90 patients in whom a diagnosis of pulmonary embolism was made with the aid of clinical, laboratory, or autopsy findings at the Graduate Hospital of the University of Pennsylvania in Philadelphia between Aug. 1, 1955, and Jan. 31, 1957. Roentgenographic examination of the chest was secured after the onset of symptoms attributable to embolism in 72 of the 90 patients. Abnormal shadows were observed in the roentgenograms of 60 of these patients. Pleural effusions observed in 33 patients and homogeneous shadows resembling those produced by pneumonia and observed in 27 patients were the commonest findings. Elevation of the diaphragm was noted in 21 patients, usually in association with some parenchymal abnormality. Linear shadows, presumably representing focal areas of atelectasis or small interlobar effusions, were observed in 19 patients.

Shadows resulting from embolism appeared rapidly after its onset. Abnormal findings were observed as frequently in roentgenograms made within 24 hours of the onset of symptoms as in those made subsequently. Shadows resulting from embolism were slow to resolve. Abnormal findings cleared within a week in 5 patients and persisted for more than 4 weeks in 19 patients. The correct diagnosis was suggested by the roentgenologist in 10 patients in whom the possibility of pulmonary embolism had not been clinically considered. The diagnosis of embolism was suggested by him in only 39 patients (54% of the 72 patients). His failure to consider this diagnosis in the other patients must be attributed to misconceptions concerning the roentgenologic criteria for diagnosis of pulmonary embolism and lack of familiarity with the clinical manifestations of the disease. The alert roentgenologist will consider pulmonary embolism in the differential diagnosis of every acute cardiorespiratory illness. He will suggest this as a possibility in all patients with pulmonary and pleural shadows resembling pneumonia and pleurisy. Not infrequently, he will recognize characteristic roentgenographic patterns that will provide strong evidence for a diagnosis of pulmonary embolism even when typical clinical manifestations may be absent. The frequency with which pulmonary embolism is clinically diagnosed depends largely on the frequency with which the roentgenologist calls attention to the possibility of this disease.

Treatment of Thyrotoxicosis with ^{131}I: A Review of 500 Cases. G. W. Blomfield, H. Eckert, M. Fisher and others. Brit. M. J. 1:63-74 (Jan. 10) 1959 [London].

The authors describe the results obtained in 500 thyrotoxic patients (398 women and 102 men) treated with radioiodine (I^{131}) in two centers in Sheffield from 1949 to 1958. The following groups were regarded as suitable for treatment with I^{131}: (1) patients over 45 years of age; (2) younger patients in whom there is associated disease, particularly cardiovascular complications, probably reducing the life expectancy to less than 20 years; (3) patients who have relapsed after thyroidectomy; (4) patients who have not remained euthyroid after a course of treatment with antithyroid drugs or have shown toxic reactions to these drugs and who are considered unsuitable for or have refused partial thyroidectomy. Pregnancy is a complete contraindication for this form of treatment.

The intention was to deliver about 7,000 rads in the treatment of the patient with uncomplicated thyrotoxicosis. A slightly greater dose was chosen for patients with severe hyperthyroidism, nodular glands, or disabling cardiac complications. It was regarded as advisable to give slightly smaller doses in the treatment of patients with postoperative recurrences and milder cases with small smooth glands. The calculation of the number of millicuries of I^{131} to be given to the patient to provide the intended rad dose to the thyroid depends on the size of the gland and the proportion of the dose taken up by and retained in the gland. A preliminary tracer test with I^{131} was made, and the uptake at 48 hours was measured to forecast the anticipated uptake of the therapy dose. The formula used in the calculation was explained in an earlier report. The mass of the thyroid was estimated from the results of palpation by several experienced observers. The patients were seen at the thyroid clinic monthly for 2 months after therapy and thereafter at longer intervals. A repetition of treatment was not considered so long as any improvement was noticeable, and at least 3 months had to elapse after the first treatment before a new treatment was given.

After the first treatment 59% of the patients patients became euthyroid and 10% hypothyroid. A further 21% became euthyroid after 2 or more treatments. Hypothyroidism occurred in all in 12% of the patients. A study of the factors that influence the response to treatment revealed that the gland size was the most important, but this was difficult to determine accurately. Hypothroidsm occurred most frequently in patients with small glands, the size of which was probably overestimated. The age of the patient and wide variations in the uptake and the half-life of I^{131} in the thyroid did not have any consistent effect on the clinical result. Patients with tracheal compression or distortion due to thyroid enlargement were treated. No symptoms due to tracheal compression occurred after therapy, and the subsequent shrinkage of the gland restored the tracheal abnormality towards normal. The irradiation dose to the plasma was calculated for the younger patients. The mean plasma dose was 25 rads, but this was greatly exceeded in a few of the patients receiving 2 or more treatments. Several normal pregnancies occurred after therapy.

Thirty of the 500 patients had died at the time of the completion of this review. In 18 patients death was due to cardiovascular disease; in 4 the cause was carcinoma; and in the remaining 8 death was predominantly due to respiratory infections. The carcinomas responsible for death were in the breast, ovary, rectum, and thyroid. The patient with carcinoma of the thyroid died 9 months after treatment.

Malignant Irradiation for Benign Conditions. B. Cannon, J. G. Randolph and J. E. Marray. New England J. Med. 260:197-202 (Jan. 29) 1959 [Boston].

Some of the disabling and life-endangering consequences of the use of irradiation in the treatment of benign conditions are discussed on the basis of 165 cases from the records of the Massachusetts General Hospital in Boston and from personal files. In many patients it proved impossible to ascertain the exact dosages of irradiation administered, because the treatment was given many years ago by physicians who have died or whose records are either incomplete or unavailable. In professional workers the exposure was in small amounts during a period of many years. Clinical and pathological evidence of chronic irradiation damage in the diseased tissues was enough to incriminate the irradiation exposure as a major factor in the changes observed.

In the 32 patients who had received irradiation (usually multiple treatments) for plantar wart, the average time lapse from exposure to surgical treatment was 5½ years. Nineteen patients with abnormal skin conditions (eczema, psoriasis, lichen planus, and the like) treated with x-rays had severely injured skin and soft tissue. The mean latent period between exposure and skin breakdown in these patients was 14 years. The average time lapse before surgical treatment was requested by 14 patients who had received irradiation in infancy for isolated hemangiomas was 20 years. In 12 patients tissue damage resulted from irradiation for the removal of unsightly hair. This method of epilation was popular about 30 years ago, and its damaging effects are still being observed.

The sequels of irradiation for acne were especially deplorable, since cancer developed in 9 out of 10 patients. A number of other patients with acne scars gave a history of roentgen-ray irradiations. They are not included in this report, because surgical treatment was not recommended, but there is evidence that neoplastic changes can be anticipated in their skins. A number of other patients had received roentgen-ray irradiations sufficient to produce skin damage for such lesions as Dupuytren's contracture, pruritus, pulmonary tuberculosis, goiter, rheumatism, spondylitis, furuncle, gallbladder colic, and cervical adenitis.

Cancer was found in 36 of 165 patients (22%). The interval between irradiation exposure and the establishment of a diagnosis of cancer ranged from 5 to 50 years. In 5 cases the interval was over 40 years. Cancer may still develop in patients more recently exposed. Fourteen of the 36 cancers were of basal-cell type. This is contrary to the accepted teaching that only epidermoid carcinoma is found in irradiated areas. With one exception, a physician's hand, all basal-cell lesions occurred on the face. Surgical therapy should be prompt and thorough, since only by prophylactic excision of all severely injured skin can the malignant transition be avoided. Seventy-six of the 165 patients were presumably cured after one surgical procedure. An additional 15 patients required a second excision. The remainder needed multiple operations.

Some Observations on the Treatment of Radio-Resistant Tumours. G. E. Flatman. J. Fac. Radiologists 10:21-26 (Jan.) 1959 [Bristol, England].

While generally the histological picture indicates the likely degree of radiosensitivity, there are cases in which it is impossible to prejudge what control irradiation will achieve. A well-known example of this variation is the squamous-cell carcinoma of the tongue, a tumor of moderate radiosensitivity which occasionally proves to be completely radioresistant. Conversely, a proportion of the so-called radioresistant tumors, for example, soft-tissue sarcoma, will respond to irradiation. Supervoltage treatment techniques, which have become available in recent years, make possible the delivery of higher tumor dosages with less damage to surrounding normal tissues and minimal constitutional upset. Evidence is now available showing that some of the so-called radioresistant tumors can be effectively treated by irradiation.

At Mount Vernon Hospital, Northwood, England, many of these tumors have been irradiated—in the past by conventional irradiation techniques, and during the last 4 years by means of either the

4-megavolt linear accelerator or the 1,500-curie Theratron cobalt unit. Irradiation was carried out (1) when there was evidence that surgery alone would not cure the patient, (2) when surgery was impossible on account of the size or situation of the tumor, and (3) when palliation seemed possible despite the advanced state of the tumor. The histories of 7 patients who were treated either by irradiation alone or by combined irradiation and surgery illustrate the value of radiotherapy in the management of some of the radioresistant tumors. A tumor dose of 5,000 r was applied over 5 weeks in the form of deep x-ray treatment (250 kv.) to an osteogenic sarcoma involving the head, neck, and lesser trochanter of the left femur of a 27-year-old woman (case 1). This produced symptomatic relief, but recalcification was slow, and a year later a further dose of 3,500 r was given. After this second course of treatment the bone sclerosed. Later a necrotic ulcer resulting from external trauma made surgery necessary, and histological examination of the operation specimen failed to reveal any viable tumor cells.

In a 41-year-old man (case 2) a spindle-cell sarcoma at the site of operation in the fibula was irradiated with the Theratron cobalt unit to a dose of 7,500 r. A roentgenogram taken 7 months after completion of treatment showed sclerosis of the affected bone with diminution in size of the soft-tissue mass. The patient was symptom-free 18 months later. In a 2-year-old girl (case 3) a fibrosarcoma of the right antrum was treated by means of the linear accelerator to a tumor dose of 7,900 r. More than 12 months after this treatment, the child was free from active disease.

A fibrosarcoma at the back of the thigh of a 69-year-old patient (case 4) was irradiated with the Theratron cobalt unit; 3,400 r was given in 4 weeks, and after 3 weeks' rest a further 4,500 r was given in 6 weeks. The tumor diminished in size, but subsequently broke down, and guillotine amputation was carried out. Examination of 18 blocks of the tumor failed to reveal any viable cells. The patient was still well 3 years later. Chordomas have been successfully treated by irradiation. This is illustrated by the history of a 69-year-old woman (case 5) in whom a sacral chordoma has been controlled by irradiation at both conventional and megavoltages for over 6 years.

Case 6 was that of a 21-year-old man with a large tumor of the right buttock. A year before a small, supposedly benign tumor had been removed from the same site. Biopsy of the recurrence showed it to be a chondrosarcoma. Irradiation was given with the linear accelerator. Later, aspiration of fluctuant material and nitrogen mustard treatment were carried out, and the patient could return to work. A 33-year-old woman with an irremovable carcinoma of the cecum (case 7) received irradiation with the Theratron cobalt unit. This reduced the size of the tumor, so that subsequent resection became possible. The patient was still free from recurrence 18 months later.

BIOCHEMISTRY

Biochemical and Hormonal Changes in Human Beings After Implantation of Yttrium 90 into the Sella Turcica. G. M. Molinatti, A. Pizzini, F. Camanni and others. Minerva med. 40:4014-4021 (Oct. 27) 1958 (In Italian) [Turin, Italy].

Biochemical and hormonal changes related to functional change of the pituitary body were studied in 34 patients with various types and different locations of neoplastic disease after implantation of radioyttrium (Y^{90}) into the sella turcica. A thorough study in time was possible in only 15 patients. The level of urine chorionic gonadotropin decreased in a few patients from 10 to 15 days after implantation of Y^{90}, whereas no change was observed in the remaining patients. No manifest change in the serum inorganic phosphorus level took place either immediately or several months after the operation, although many patients had osseous metastases. Concentration of iodized proteins in plasma showed diminished function of the thyroid gland in 7 patients in a week and in 3 patients from 40 to 60 days after implantation of Y^{90} into the sella turcica. Hypothyroidism was confirmed with the functional test of radioiodine (I^{131}). Increased total serum cholesterol levels were correlated with decreased concentrations of iodized proteins in plasma. Changes in the levels of the urinary 17-ketosteroids and 17-OH corticosteroids indicated a decrease of the function of the adrenal cortex in 6 patients of both sexes 2 weeks after the implantation of Y^{90}. Chromatographic determination of urinary 17-ketosteroid levels suggested a decrease of both gonadal and adrenal functions in 3 patients. Polyuria accompanied by hyposthenuria appeared in several patients from 3 to 5 days after implantation of Y^{90} and disappeared 2 weeks later.

Implantation of Y^{90} into the sella turcica induced an almost total functional insufficiency of the pituitary body in 8 patients (50%). The main clinical effect of the implantation was an acute hypoadrenia, which appeared within 2 weeks of Y^{90} therapy. This disorder was corrected by administration of large doses of cortisone or hydrocortisone. Myxedema developed in 2 patients, and a mild variety of hypothyroidism in another 2 within 50 to 60 days of Y^{90} therapy. Position of the implanted rods of Y^{90}, rather than their numbers, appeared to be important for the radioactive effect of Y^{90}. When the rods were lying on the

Dr. Robert Heilig Library
S. M. S. Medical College

external surface of the pituitary, necrosis of the gland was incomplete. Necrosis was almost complete if the rods were inserted into the pituitary. No cell regeneration of residual parenchyma was observed either soon afterward or after 6 months in instances in which partial necrosis of the pituitary body took place. Hypofunction of the pituitary remained unaltered. This study revealed that implantation of Y^{90} into the sella turcica induced in most patients a clear functional insufficiency of the pituitary body.

The Study of the Properdin System of the Body. A. A. Bagdasarov, R. A. Rutberg, I. L. Chertkov and others. Prob. Hematol. & Blood Transfus. (Translation from the Russian.) 3:69-73 (no. 2) 1958 [New York].

The properdin system, a new system of natural immunity recently discovered by Pillemer, consists of the serum protein properdin, magnesium ions, and 4 components of complement. The authors have made active preparations of properdin and of the yeast constituent zymosan, which reacts easily with properdin, and also of the reagents RP (serum deprived of properdin but retaining its complementary activity) and R_3 (serum deprived of the third component of complement [C_3] but retaining the activity of the 3 remaining components of complement); this made it possible to study the blood properdin level in man and animals in the normal state and in various pathological conditions. In the serum of healthy human donors, the properdin titer varied from 4 to 12 units per cubic centimeter (on the average 8 units per cubic centimeter). These results agree with those obtained by Pillemer; thus, the correctness of the authors' method for determining the activity of properdin and also the suitability of zymosan, RP, and R_3 for its titration were confirmed.

The properdin content was studied in 22 patients with various hematological diseases (acute leukemia, leukosarcoma, chronic granulocytic leukemia, lymphocytic leukemia, hypoplastic and aplastic anemia, and hemolytic anemia). No change was detected in the level of properdin in the blood of these patients. The only exceptions were patients with acute leukemia; in 2 patients examined, properdin could not be found. It may be that the disappearance of properdin in these patients was due to their poor general condition. No increase in the blood properdin content was found in 2 patients with paroxysmal nocturnal hemoglobinuria; the blood properdin level in one of these patients, who was severely ill with pronounced hemolysis, was lower (4 units per cubic centimeter) than in the other patient with a milder form of the disease (8 units per cubic centimeter).

In experiments on dogs and rats in which th properdin level in the blood was determined before and after irradiation with roentgen rays changes in the activity of the properdin system were observed, which confirmed those reported by Pillemer in animals with acute irradiation sickness. In 25 patients with chronic irradiation sickness developing as a result of radiotherapy fo malignant neoplasms, the blood properdin tite was determined; it was found to be within normal limits (4 to 12 units per cubic centimeter) i 24. In only one patient was the properdin conten in the blood lowered to 2 units per cubic centimeter. This lowering could hardly be attribute to irradiation sickness, since in this patient th disease was not severe. It may be assumed tha the lowering of the properdin content in this patient was due to the trauma of a surgical operatio not long before the determination of the properdi in the blood.

Serum Cholesterol in Man: Diet Fat and Intrinsic Responsiveness. A. Keys, J. T. Anderson an F. Grande. Circulation 19:201-214 (Feb.) 1959 [New York].

The serum cholesterol concentration in ma is strongly influenced by both the amount an the kind of fat in the diet, and it is necessary t distinguish among 3 classes of fatty acids, namely, saturated, monoenoic, and polyenoic. Data obtained from a number of dietary experiments i man yielded a formula by which the response in the serum cholesterol level to changes in die can be predicted. The reliability of this formula was tested by the authors on 24 stabilized schizophrenic men who were physically healthy an were maintained on a regimen of constant activity The effects of various types of fatty acids on th serum cholesterol levels of these men were studied. The results of controlled dietary experiment performed on these men justified the following conclusions: 1. In man, oleic acid glyceride in th diet is the equivalent of equal calories from carbohydrate with respect to the effect on the serum cholesterol level. 2. The glycerides of saturated fatty acids in ordinary food fats raise the serum cholesterol level and the glycerides of unsaturated fatty acids (mainly linoleic acid) lower it; in thi respect it requires slightly more than 2 Gm. o linoleic acid to offset the effect of 1 Gm. of a saturated fatty acid, such as stearic or palmitic acid 3. Intrinsic relative hypercholesteremia is generally associated with relative hyperresponsiveness to dietary fat changes. 4. These relationships allow reasonably accurate predictions of group average responses in serum cholesterol level to given changes in dietary fats.

BOOK REVIEWS

Don't Worry About Your Heart. By Edward Weiss, M.D. Cloth. $3.95. Pp. 203. Random House, Inc., 457 Madison Ave., New York 22; Random House of Canada, Ltd., 1149 King St., W., Toronto 2, Canada, 1959.

Within the past few years numerous books have been written for laymen who suffer from heart attacks or who have relatives with heart diseases. Some of these have been factual without being interesting, some have been alarming, and some have been written from a biased or faddist viewpoint. A few have been informative, reassuring, and written in such a manner as to be readable and helpful for the patient. This author has approached the problem largely from the viewpoint of the patient and his fears and anxieties. His notable experience in the field of psychosomatic medicine is clear in his presentation. After the introductory chapters succeeding sections of the book cover anxiety and the normal heart, high blood pressure and its management, and anxiety and the diseased heart. The last section includes chapters on coronary heart disease; work, worry, and heart disease; sexual problems and heart disease; the "anniversary" reaction; reactions to heart attacks; valvular heart disease; the psychology of heart surgery; and a brief chapter on cerebral vascular disease. Although there are numerous references to treatment of the organic aspects of heart disease and high blood pressure, the author has concentrated on the question of the relationship of emotion to heart disease. His style is lucid and readable, and he has illustrated his points with many brief case histories. Most patients should find this book helpful and reassuring.

Fracture Surgery: A Textbook of Common Fractures. By Henry Milch, M.D., and Robert Austin Milch, M.D. With chapter on anesthesia by Herbert D. Dubovsky, M.D., Director of Anesthesiology, Easton Hospital, Easton, Pa. Cloth. $17.50. Pp. 470, with 671 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1959.

This book is divided into four major sections. Most of the illustrations are reproductions of roentgenograms, and a large proportion of these present complicated reconstructive problems. Diagrammatic illustrations would have been more forceful for the teaching of students and young surgeons. In the preface the authors state that the book makes no pretense of being either a roentgenographic atlas or a complete treatise on fractures. The problems discussed are thoroughly covered, with the inclusion of more than one solution in most instances. The terminology used in certain chapters is not in common usage in many medical centers.

Chapter 8 is entitled "Compound Fractures"; most orthopedists are now using the term "open fractures" for this problem. In the text, the terms "open" and "compound" are both used. The chapter on axial malalignments is beautifully written and illustrated, but it would have been more effective if the terminology used for the various types of deformities had been directly correlated with the more common nomenclature. Many of the chapters include roentgenographic illustrations of successful reconstructive operations for malunion or nonunion. Only occasionally is there a specific presentation of the operation recommended. The bone graft procedure for persistent nonunion of the tibia, as illustrated in figures 428 and 429, is an exception. Many of the diagrammatic illustrations have been previously published, either in medical journals or by commercial instrument companies. This textbook should be of interest to surgeons with a substantial background in orthopedic and traumatic surgery. It does not appear to be a practical textbook for students or young orthopedists, except as a background reference for certain specific subjects.

Principles of Gynaecology. By T. N. A. Jeffcoate, M.D., F.R.C.S., F.R.C.O.G., Professor of Obstetrics and Gynaecology in University of Liverpool, Liverpool. Cloth. $15; 75 shillings. Pp. 669; 27, with 436 illustrations. Butterworth & Co. (Publishers) Ltd., 88 Kingsway, London, W. C. 2, England; 1367 Danforth Ave., Toronto 6, Canada, 1957.

This book is intended primarily for the undergraduate, but its complete coverage should make it of value to the hospital resident and general practitioner. It is an exceptionally comprehensive, lucid, and practical presentation, with particular emphasis on the psychological and medical rather than the surgical aspects of obstetrics and gynecology. A wide range of subjects is covered, including history-taking, ovarian function, infertility, backache, pregnancy, abortion, and dysmenorrhea and other gynecologic conditions, not only from the pathological aspects but also from the emotional side. Neglected areas such as hysterectomy and its aftermath and preoperative and postoperative management are emphasized. There are excellent sections on female urology and proctology. The pathology of menstruation, breast function, and tumors of the reproductive tract is described in detail. Ample illustrations are provided. Intersexuality, pseudohermaphroditism, and neuroendocrinologic changes involving ovulation and menstruation are adequately covered. The text contains sound premarital advice and discusses contraception and

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

marital guidance. It is meant to add to, rather than replace, clinical instruction so that the student will not have to cull the literature. The focus is narrowed to the nonsurgical aspects of gynecology, because these far exceed the surgical problems encountered. This presentation emphasizes the art as well as the science of gynecology. It is highly recommended for the student, the general practitioner, and even the specialist.

Pain. By Harold G. Wolff, M.D., Professor of Medicine (Neurology), Cornell University Medical College, New York City, and Stewart Wolf, M.D., Professor and Head, Department of Medicine, University of Oklahoma School of Medicine, Oklahoma City. Publication number 333, American Lecture Series, monograph in Bannerstone Division of American Lectures in Physiology. Edited by Robert F. Pitts, M.D., Ph.D., Professor of Physiology and Biophysics, Cornell University Medical College. Second edition. Cloth. $4.25. Pp. 121, with 20 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

The authors have added a few new items of practical value which were omitted in the earlier edition. The current edition is in the nature of a brief synthesis, reflecting current thinking about pain from the viewpoint of some of the important developments in the past. The book also is designed to be of use to students and practitioners who are confronted with day-to-day problems in the diagnosis and management of painful conditions. Drs. Wolff and Wolf are authorities on the subject of pain, and this book presents a point of view not commonly recognized by physicians and others who must somehow overcome problems of pain. This book should greatly benefit the physician who must deal with such problems and, indirectly, should have some useful results for the patients as well. It is printed on good paper and is easily read. It is indexed and contains an excellent up-to-date list of references on all the various aspects of the problem of pain.

Trauma and Disease: Selections from the Recent Literature. Edited by Alan R. Moritz, M.D., Professor of Pathology and Director of Institute of Pathology, Western Reserve University, Cleveland, and David S. Helberg, J.D. Cloth. $17.50. Pp. 903. Central Book Company, 850 De Kalb Ave., Brooklyn 21, N. Y., 1959.

This volume consists of previously published articles which are reprinted in part or in their entirety, with some explanatory or critical editorial comments. As they frankly admit in their introduction, "the editors have undertaken this republication of the writings of others, dealing with trauma in the causation of disease, with considerable misgiving. Frequently, in our opinion, the evidence presented by the author did not warrant the conclusions drawn from it. Frequently, we were not sufficiently familiar with the subject matter under discussion to be able to judge either as to the adequacy of the evidence or as to the validity of the conclusions drawn from it." The editors believe, however, that these difficulties are at least partially compensated by the fact that many of the articles which they reprint "represent real advances in the field of legal medicine and will almost surely serve to improve the quality of justice in the evaluation of personal injury cases." A large portion of the collection is devoted to articles on stress, but it is presumably owing to the editors' emphasis on problems of jurisprudence that the somatic aspects of stress and the general adaptation syndrome, as well as the biochemical basis of the diseases of adaptation, have been neglected at the expense of legal considerations and the discursive treatment of emotional stress factors. Unfortunately, the volume is not provided with an index, which makes orientation in this large book difficult.

Essentials of Human Reproduction: Clinical Aspects, Normal and Abnormal. Edited by Joseph Thomas Velardo. Contributors: Robert W. Brown, M.D., and others. Cloth. $13.50. Pp. 270, with illustrations. Oxford University Press, 417 Fifth Ave., New York 16, 1958.

This volume represents the collaborative efforts of 13 physicians and research workers in the field of clinical endocrinology to present both the normal and abnormal aspects of human reproduction. After a general introductory chapter on sex hormone relationships the topics discussed include ovulation, menstruation, endocrine changes during pregnancy, disturbances of pregnancy, gynecologic disorders, and infertility. Other chapters are devoted to the anatomy and physiology of the placenta and to endocrine disorders in the male and female reproductive organs. The material is well integrated and each topic is covered in a comprehensive and up-to-date manner. Each chapter concludes with an extensive bibliography and the text is liberally illustrated with excellent reproductions, including both photomicrographs and color plates. This book can be recommended as an authoritative text in the field of human reproduction.

Practical Clinical Biochemistry. By Harold Varley, M.Sc., F.R.I.C., Biochemist, Manchester Royal Infirmary, Manchester, England. Second edition. Cloth. $6.50. Pp. 635, with illustrations. Interscience Publishers, Inc., 250 Fifth Ave., New York 1; William Heinemann, Ltd., 99 Great Russell St., London, W. C. 1, England, 1958.

In the three years since the publication of the first edition of this book on clinical biochemical tests and interpretations enough new information has become available in this field to warrant extensive revision and the publication of a new edition. The chapters on hormones and proteins have been greatly expanded and rewritten, and new sections on hydroxyindoles, transaminases, and mucoproteins have been included. Newer developments in analytical techniques have been added in many chapters throughout the book. The arrangement of the chapters and the presentation of material within each chapter closely follows that of the first edition. Reference is made to recent American and English literature.

QUESTIONS AND ANSWERS

LOW BACK PAIN

To the Editor:—*A company physician for an organization that manufactures heavy farm equipment is faced with the problem of low back pain in employees who do heavy manual labor. How can the company be protected against alleged liability for low back injuries? What are the pros and cons of obtaining a roentgenogram of the lumbosacral spine as part of the preemployment examination?*

Marion M. Sumner, M.D., Hutchinson, Kan.

Answer.—It may be presumed that the goals of the inquiring physician are to help prevent back injuries for the sake of the welfare of the employees and to help assure that the company by which he is employed is held liable only for true disability suffered as a result of employment. With respect to the prevention of back injuries, the physician is in a position to contribute, although for a truly effective program with this goal there must be an effort on the part of supervisors and safety personnel to accomplish the educational efforts and rearrangement of work procedures indicated to minimize the likelihood of back injuries. The physician's principal opportunity in preventing such injuries is the chance that he has to advise against the placement or continuation in any work involving back strain of an applicant for employment, or an employee, whose medical history, physical examination, or (if obtained) roentgenograms indicate a decreased fitness for work requiring a healthy back. A complete history and physical examination will often reveal a lack of fitness with respect to the back. X-raying the lower portion of the back of those who are to do heavy work often reveals contraindications to such work when the medical history and physical examination were nonrevealing in this way.

The major criticisms of preplacement x-ray examinations of the back have usually been concerned with radiation exposure or with the interpretation of, and action taken on the basis of, positive findings. With respect to the first of these problems, it is true that an applicant for employment in a position involving heavy labor who is so x-rayed and not employed because of a positive finding might possibly seek other work and have back x-rays performed by a number of other potential employers within a relatively short period of time. Some steps that might minimize this likelihood suggest themselves, and the risk involved in it must be weighed against the risk of significant back disabilities which might result from failure to detect contraindications to heavy work.

With respect to the second, some physicians have counseled against the employment of persons who have positive findings on roentgenograms of the back, the significance of which is limited and which would probably not truly influence the applicant's fitness for heavy labor (such as a small spina bifide occulta). Where this has occurred, early in the use of such roentgenograms in the railroad industry for example, it has probably resulted from the conviction of those involved that any positive roentgenographic finding in a case which is the subject of subsequent litigation unjustly influences awards made and even seems to result in the making of awards when no other evidence of an injury or of disability can be demonstrated.

With respect to the prevention of fraudulent claims and avoiding the placement in heavy work of persons who are not aware of or who conceal significant back disease or previous injuries, it seems self-evident that roentgenograms of the lumbosacral spine can be useful. As a matter of perspective, however, one must keep in mind the debatability of endorsing the employment for heavy work of a man with a back which is perfect roentgenologically but whose past behavior has revealed evidences of irresponsibility or perhaps even lack of integrity, while counseling against employment of an honest, responsible, properly motivated man who might even have a history of athletic activities, military service, and previous heavy labor without ill effects but who happens to have a roentgenologic finding of doubtful significance. In recent years, a number of helpful reports on this subject have appeared. One which illustrates impressively favorable results enjoyed largely on the basis of preplacement x-ray examinations of the lower part of the back is that by Becker (*Indust. Med.* 24:486, 1955).

CAPILLARY INTEGRITY

To the Editor:—*How can a capillary hemorrhage be differentiated from the simple passage of the blood cells through the walls of the capillaries?*

Aaron N. Gorelik, M.D., New York.

Answer.—Normally the integrity of the capillary wall does not allow the passage of red blood cells. Several factors, such as inflammation and platelet deficiency, damage the integrity of the capillary wall and allow free passage of erythrocytes into the surrounding tissue. The degree of damage to the capillary wall is one of the factors determining

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

the size of the hemorrhage. Presence of petechiae characterizes the abnormality of the capillary wall. Such small hemorrhages can readily be seen if they are present on the skin, mucosa, or eye grounds. Microscopic examination of tissue is necessary to determine the degree of hemorrhage, if present, in tissues or organs.

INFECTIOUS HEPATITIS

To the Editor:—*The wife of a patient who had infectious hepatitis received an injection of gamma globulin. Although she was free of symptoms and had no jaundice, results of the laboratory tests done the next day were reported as follows: serum glutamic oxalacetic transaminase level, 485 units, and serum bilirubin level, 0.7 mg.%. Six days later the transaminase level was 400 units, serum bilirubin level 0.3 mg.%, and cephalin flocculation 2+ after 24 hours and 2+ after 48 hours. Thirteen days after the first test the serum glutamic oxalacetic transaminase level was 185 units and the thymol turbidity 3.4 units. The patient was confined to bed for 14 days. She has remained well since then (24 days). If it is agreed that this patient had an enzymatic rather than a subclinical form of infectious hepatitis, should she be treated with bed rest, diet, and similar measures until the enzyme levels have returned to normal values? Should she be considered to be a carrier and therefore be isolated? In turn, should those who had close working association with her receive similar attention? Would the routine use of enzyme studies in household contacts be of value in curbing the spread of infectious hepatitis?*

Fritz F. Blumenthal, M.D., Middletown, N. Y.

Answer.—It would seem likely that this patient did have acute hepatitis and that she should be treated in the usual fashion until results of the serum transaminase and sulfobromophthalein retention tests are normal. It is likely that she was a carrier during the acute phase of disease and possibly longer, and so the usual enteric precautions are recommended. Those persons in close working association with her at the time might profit by receiving normal human gamma globulin. This consultant believes that the routine determination of serum transaminase level in household contacts would be of value in detecting subclinical cases of hepatitis.

Answer.—The term "enzymatic" form of infectious hepatitis is open to serious question. The use of this term would imply that the entity was a derangement of enzymes rather than damage by a virus to liver cells. In view of the danger of patients with asymptomatic infectious hepatitis developing a fulminant and fatal form of the disease or postnecrotic cirrhosis, it would be well for neither the physician nor the patient to be lulled false security. The absence of jaundice and symptoms would not preclude this patient from consideration as having a case of infectious hepatitis. If symptoms were present, the case would be one of anicteric or nonicteric infectious hepatitis. Both the asymptomatic and nonicteric forms of infectious hepatitis would be considered subclinical and would depend on results of laboratory tests for the diagnosis.

From the findings on serial determinations of the transaminase level it could be assumed that this patient had recent hepatocellular damage. The serum bilirubin level and thymol turbidity were normal and the cephalin flocculation of 2+ is of questionable significance. The diagnosis of asymptomatic or subclinical hepatitis in this case depends on the knowledge of intimate contact with a person with an obvious case of infectious hepatitis and the persistently elevated serum transaminase levels. Because of the relatively high initial serum transaminase level (485 units), bed rest for two to three weeks and a nutritious diet would be good treatment. At the end of this period, if there were no symptoms and the transaminase level had stabilized (not necessarily returned to normal), the patient could be made ambulant. Subsequent serial determinations of the transaminase level should not reveal an elevation of more than 50 units. An elevation of 50 units would indicate the need for further bed rest.

The patient should definitely be considered a carrier and special precautions taken with respect to stools, venipuncture, and parenteral treatment of any kind. Inasmuch as proof that a person is a carrier can be established only by the injection of blood into human volunteers or by the ingestion of properly prepared material from the feces by such volunteers, all persons working in close association with the patient should be considered as potential carriers and as possibly having subclinical cases. If feasible, liver function tests, including enzyme studies, should be done to determine the clinical status of these persons. It would also be well to give each of these contacts an injection of gamma globulin, which may abort the disease even during the incubation period. The routine use of enzyme studies would be of definite value in helping to identify whether household contacts suffer from the asymptomatic or nonicteric form of infectious hepatitis. Such identification with subsequent administration of gamma globulin would protect these persons. In addition, investigation of the water, food, and milk supply, as well as sanitary measures in the disposal of feces, would be of value in curbing the spread of infectious hepatitis.

WESSON OIL

To the Editor:—*Is Wesson oil hydrogenated?*

M.D., New Jersey.

Answer.—Wesson oil is a liquid vegetable oil made from cotton seed. It is not hydrogenated. It contains 50% linoleic acid and 25% oleic acid.

HOUSE ACTS ON LOAN INSURANCE FOR NURSING HOMES

Both of the catch-all housing bills offered to the House in the session's first major fight over economy in government contained loan insurance provisions aimed at stimulating construction of proprietary nursing homes.

The House, voting mainly on party lines, cleared the 2.1-billion-dollar Democratic housing bill by a 261 to 160 tally despite warnings by Republicans that the President might veto it.

The floor action came after the House Rules Committee, which had held up for weeks a measure cleared by the House Banking Committee, finally voted eight to four to allow consideration by the full House. However, the bill was sent to the floor under a procedure allowing a substitute and less costly measure to be offered as an alternative.

The administration promptly endorsed the substitute, sponsored by Rep. A. S. Herlong Jr. (D., Fla.) and backed by most Republicans in the House.

The sections of both bills dealing with proprietary nursing homes were identical. A Senate-approved housing bill contained a somewhat different nursing home provision. A conference committee composed of top members of the House and Senate Banking Committee had the responsibility of working out differences between the Senate and House versions of the housing legislation.

The House and Senate bills authorized the Federal Housing Administration to insure loans for construction or improvement of private nursing homes. Under the House version individual loans up to 1 million dollars but not to exceed 75% of the cost of the installation could be insured by the agency. The Senate measure provides that individual loans up to $12,500,000 and not over 75% of the cost could be insured.

State Hill-Burton authorities, who supervise the program of federal grants to help hospital construction, would pass on the eligibility of nursing homes for the mortgage guarantees. However, the Senate voted to allow nursing homes rejected under this procedure to appeal to the FHA. There was no appeal provision in the House measures.

The American Medical Association has supported the nursing home provisions.

The most controversial issue was public housing. The committee bill called for an expanded program of federal construction of low-cost housing units. The Herlong bill did not provide for any new units.

The substitute bill provided about 1.3 billion dollars for various housing programs, compared to more than 2 billion dollars in the committee bill, which opponents contended would throw the budget out of balance.

SENATE CLEARS INTERNATIONAL MEDICAL RESEARCH BILL

The Senate approved and sent to the House the measure setting up a new National Institute for International Health and Medical Research. The outcome was a foregone conclusion, since 64 senators of both parties had sponsored the measure.

The new Institute would bring to eight the number of branches of the National Institutes of Health, a part of the Public Health Service.

The bill, introduced by Sen. Lister Hill (D., Ala.), chairman of the Senate Labor and Public Welfare Committee, authorizes $50,000,000 annually for the international program. It seeks to encourage and support planning of essential research on a world-wide basis.

The administration had expressed some misgivings about some details of the measure. Although the administration itself did not actively oppose the measure, Senate Republican leader Everett M. Dirksen (R., Ill.) led a fight against it. He told the Senate that it might unbalance the budget.

Senator Hill said the measure would help mobilize the world's best medical brains "against the killers that have baffled mankind through the centuries."

One objection by Arthur S. Flemming, Secretary of Health, Education, and Welfare, was that the $50,000,000 authorization might lead other nations to expect too much of the United States.

The American Medical Association has endorsed the measure. Dr. Gunnar Gundersen, A. M. A. President, in backing the legislation, suggested to the Senate committee that the program should be primarily one of research rather than construction of research facilities.

Although the measure did authorize grants for the improvement and construction of research facilities, the committee declared that the language is "not intended to authorize any large-scale brick and mortar program."

WELLCOME & CO. (U.S.A.) INC., Tuckahoe, New York

The bill would place the research program under the U. S. surgeon general, provide a 19-member advisory council with control over financial grants, and authorize grants to the World Health Organization and other international groups for research and research training.

A specific prohibition against the supporting of operational public health or medical care programs was included.

WITNESSES BACK RADIATION HEALTH RESPONSIBILITY TRANSFER

Transfer of responsibility for radiation health protection from the Atomic Energy Commission to the Public Health Service was endorsed by most witnesses before a congressional committee, but as of this writing the administration still had not taken a position.

The issue is being considered by a Senate labor and public welfare subcommittee headed by Sen. Lister Hill (D., Ala.), who has introduced a measure to carry out the shift.

The legislation was prompted by the recent recommendation of the National Advisory Committee to the Public Health Service. Chairman of the civilian advisory group, Dr. Russell H. Morgan, professor of radiology at Johns Hopkins University, told the subcommittee that he considered it "unwise" for the same agency that handles promotion of nuclear energy uses to be responsible also for public safety aspects.

Dr. Richard H. Chamberlain, professor of radiology at the University of Pennsylvania and representing the American College of Radiology, supported the measure. But he said government regulation was only a partial answer and shouldn't interfere with the needed use of x-rays.

Bernard J. Conway of Chicago, speaking for the American Dental Association, advised a plan with "a minimum of federal control or sanctions."

The bill doesn't specify just how the PHS would carry out a supervisory program but merely directs the agency to study the question and recommend a detailed program by next February.

Dr. Berwyn F. Mattison, executive director of the American Public Health Association, proposed a "crash program" to assure adequate health protection "lest the rapidly expanding advances in nuclear energy far outstrip corresponding safeguards for the public."

Another witness, Dr. Herman E. Hilleboe, commissioner of health of New York state, said control over sources of radiation should be transferred to the states as soon as they could handle the job.

POLIOMYELITIS CASES RISE; VACCINATIONS URGED

The Public Health Service warned that almost twice as many cases of paralytic poliomyelitis have been reported during the first four months of 1959 as during the same period last year. The increase, coming on top of a 45% jump in incidence in 1958, points up the need for a renewed vaccination effort across the nation, PHS said.

A total of 283 cases has been reported so far in 1959, compared with 147 for the same period a year ago. Dr. John D. Porterfield, acting U. S. surgeon general, said, "We are at least two months away

STUDY OF PATIENTS WITH HIP ARTHROPLASTY AT MASSACHUSETTS GENERAL HOSPITAL

Otto E. Aufranc, M.D.
and
Elliot B. Sweet, M.D., Boston

SINCE the conception by Smith-Petersen,[1] in 1925, of the principle of mold arthroplasty for treatment of diseases of the hip more than 1,500 mold arthroplasties have en performed at the Massachusetts General Hos- al, most of them since the evolution of the Vital- m mold in 1938. Believing that the surgical prin- ples and postoperative management of arthro- asty were well developed by 1945, we took our ses for study from among those patients operated since Jan. 1, 1946. An examination of the entire oup of patients was impractical because of their ographical distribution.

The late results of mold arthroplasty for disease of the hip were studied in 171 patients who were available for reexamination five or more years after the operation. Among these patients there were 201 mold arthroplasties to be reviewed, 81 (the largest group) for degenerative arthritis and 51 for congenital dislocation and subluxation. Ability to function and freedom from pain were assessed for each patient. Results were classified as excellent, good, or satisfactory in 164 hips (81.5% of operations among the 171 patients) and unsatisfactory in 37. The analysis showed that all the results classified as excellent were in patients in whom the disease had been unilateral and that bilateral disease was a severe handicap. Supplementary surgery was necessary in 12% of patients. These difficulties must be balanced against the excellent results frequently obtained with complete relief from pain in 27% and unlimited walking in 24% of patients.

Material

This study is a survey of Vitallium mold arthro- asties performed on Massachusetts residents in e Massachusetts General Hospital during the ears from 1946 to 1953. Ward service patients, s well as private patients of one of us (O.E.A.); e included. Patients with rheumatoid arthritis e not included because of the special problems aracteristic of this group. Arthroplasties were per- rmed on 246 hips in 213 patients. Of these 171 atients with 201 arthroplasties were examined. he original diagnoses in the series of 201 arthro-

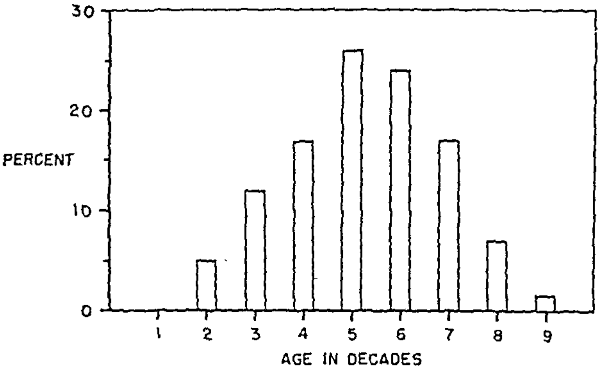
Read in part before the Boston Orthopedic Club, April 15, 1957.

plastic hips included degenerative arthritis (81), congenital dislocation and subluxation (51), old fractures of the femoral neck (23), septic arthritis and ankylosis (18), septic arthritis (14), traumatic dislocation and/or fractured acetabulum (9), old tuberculous arthritis (4), and chondroma of the acetabulum (1).

Of the 42 patients (14.5%) not included in this study 15 were dead. Eleven of these had been 63 or more years of age at the time of operation. One patient was a complete invalid due to advanced multiple sclerosis. Of the remaining 26 patients 6 were lost to follow-up, 16 were reached but failed to report for examination, and 4 have required supplementary surgery since Jan. 1, 1954. Complications in the original series of 246 arthroplasties included thrombophlebitis, 12 (5%); thrombophlebitis with pulmonary embolism, 9 (3.7%); miscellaneous, 8 (3%); subluxation, 4 (1.6%); wound sepsis, 3 (1.2%); death, 3 (1.2%); and dislocation, 1 (0.4%).



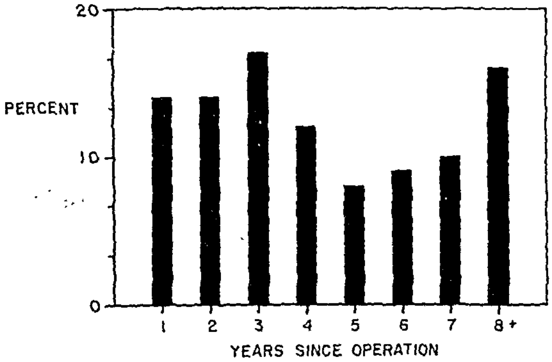


Fig. 1.—Distribution of patients by age at time of operation (*top*) and years since operation at time of study (*bottom*).

The list of complications was roughly the same as will be found in a survey of any major surgical procedure. There is a remarkable similarity between the complications found in this series and those reported by Hammond and co-workers.[2] Three postoperative deaths reported are the only

postoperative deaths in Massachusetts
Hospital experience with mold arthropla
have already been reported.[3] One patient,
died three weeks after operation of a cereb
lar accident while under anticoagulant the
thrombophlebitis. The *second death* was
year-old woman who lived for one week af
ation and never regained consciousness. A
postmortem examination revealed no obvio
of death. The third patient was a 63-year-
whose condition gradually deteriorated due
operative sepsis; he eventually died of b
pneumonia four months after operation.

Method of Study.—The patients were inte
and examined by one of us (E.B.S.). Du
interview details of medical history, develop
symptoms prior to operation, and course s
eration were reviewed following a standa
line. A pain scale and a walking scale si
those used by the Judets[4] and by Merle d'
and Postel[5] and a general function scale w
vised and applied to each patient. The d
obtained were placed on punch cards for

Physical Criteria

The patients were divided for a detailed
into three main groups: (1) those with u
arthroplasty for unilateral disease, (2) those
lateral arthroplasty for bilateral disease, a
those with unilateral arthroplasty but with b
disease. We consider that, regardless of the
sis, a patient with unilateral hip disease ha
problems and a better prognosis than does a
with bilateral hip disease. The breakdown
ical and patient evaluations according to di
as well as extent of involvement can be
figure 2, which amplifies this statement.[3]

Pain.—It was found that patients had a
curate memory of their preoperative pain as
by review of the hospital and office records
there had been no standardized method of
ing pain and other *symptoms* before this stu
carried out, it was felt that anything more
general preoperative evaluation would be
inaccurate. Therefore, we are reporting only
findings as of the time of examination. We a
the following pain scale: grade 1, no pain; g
mild and inconstant pain allowing *normal* a
grade 3, *mild* pain when walking, disappeare
rest; grade 4, tolerable pain with limited a
grade 5, severe pain when walking, marked
ited *activity*; and grade 6, *severe* pain even
interfering with sleep.

The pain chart (fig. 3) shows a good r
freedom from *disabling pain*. Only 16% were
to have a pain grade of 4 or worse. The pai
patients with mold arthroplasties described
most always different from that which the
felt before the operation. It was rarely true
pain and was located in the trochanteric and

riceps regions and described as muscle soreness. It was usually associated with "overdoing," and the patients soon learned how to avoid activities which caused this pain. It was common for a patient who had had the arthroplasty for many years to say that his hip got better with each year.

Walking.—A scale for walking endurance, regardless of the amount of support needed, was used to indicate the development of endurance as follows: grade 1, walks as much as a normal person of the same age and sex; grade 2, walks up to one mile; grade 3, walks up to one-half mile; grade 4, walks only two to three city blocks; grade 5, walks only as necessary (from room to room); and grade 6, unable to walk, leads essentially a bed-and-chair existence.

Figure 3 shows the distribution of walking endurance. Most of these patients were able to walk at least one-half mile in a sustained walk, the poorest being those with unilateral arthroplasty in the presence of bilateral disease. These patients were generally held back by the hip without the arthroplasty. It was found that 18 of the 19 patients with unilateral disease who were at least eight years since operation could walk at least one-half mile, and 18 of the 23 patients with bilateral arthroplasties, at least five years since operation, could walk at least one-half mile. Twenty-four per cent of all patients had unlimited walking endurance.

Support.—The patients were asked to use enough support to keep them from limping and to protect them from muscle fatigue and pain. The use of adequate support allows the patient more comfortable physical activity than is possible without support. As muscle strength and endurance developed we allowed them to diminish the amount of support, but to return to more support if limp or symptoms occurred.[8] After a few months the patients understood this principle and were generally cooperative. Many patients learned to carry a cane long after they had developed a gait with a barely perceptible limp in case they should inadvertently "over-do." Thus, when we say in our charts "cane, part time," we mean that the patient will use the cane out of doors but is not dependent on it. We do not refer to the patient who uses the cane for support out of doors and the furniture indoors. These statements agree with those of Blount[7] and are made to explain the common use of support among our patients. The grading was on a four-point basis, as follows: grade 1, no support; grade 2, cane part time; grade 3, cane full time; and grade 4, crutches.

Of the patients with unilateral hip disease about three-quarters used little or no support. This was not true of patients with bilateral disease; only two patients with bilateral arthroplasties walked without some sort of support for one hip or the other, and most of them used a cane to support one hip. Patients with unilateral arthroplasty in the presence of bilateral disease were about as dependent on support in walking as were those with bilateral arthroplasty. Of the entire group 30% used no support, 34% used a cane part time, 21% used a cane full time, and 15% used crutches.

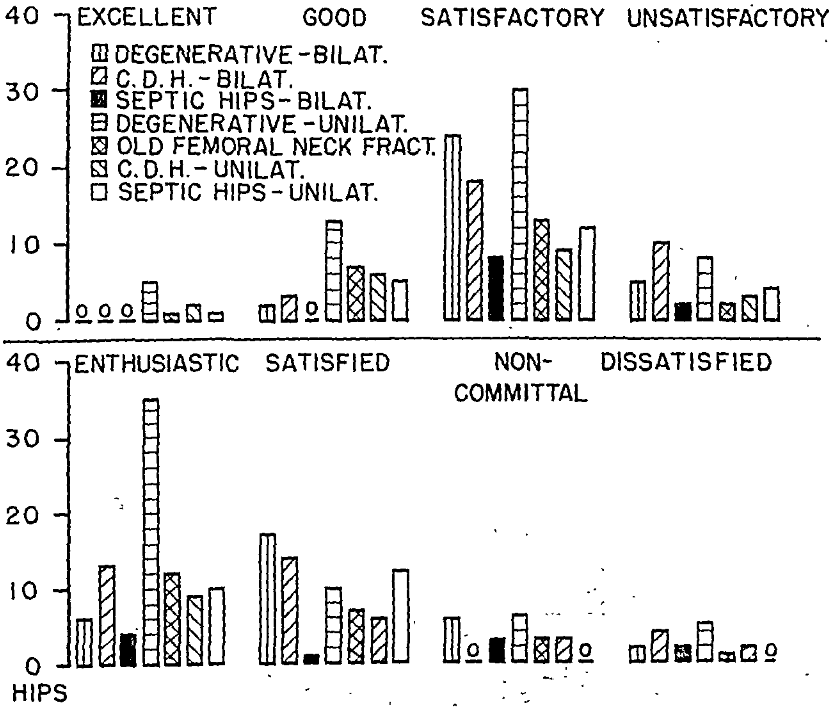

Fig. 2.—Distribution of patients by original diagnosis and two-way evaluation.

General Hip Function.—The following common hip functions were checked on each patient: ability to sit comfortably for one hour, ability to climb stairs foot after foot, ability to tie the shoe on the involved side, ability to squat, and ability to cross the involved leg over the opposite leg.

Only 12 patients out of the entire group were unable to sit comfortably for one hour. This was in contrast to more than two-thirds who had not been able to sit comfortably before operation.

The ability to go up stairs, one foot after the other, is a measure not only of the amount of flexion of the hip but also of its stability. Nearly two-thirds of the patients with mold arthroplasty were able to go up stairs one foot after the other, and about one-half were able to squat.

plastic hips included degenerative arthritis (81), congenital dislocation and subluxation (51), old fractures of the femoral neck (23), septic arthritis and ankylosis (18), septic arthritis (14), traumatic dislocation and/or fractured acetabulum (9), old tuberculous arthritis (4), and chondroma of the acetabulum (1).

Of the 42 patients (14.5%) not included in this study 15 were dead. Eleven of these had been 63 or more years of age at the time of operation. One patient was a complete invalid due to advanced multiple sclerosis. Of the emaining 26 patients 6 were lost to follow-up, 16 were reached but failed to report for examination, and 4 have required supplementary surgery since Jan. 1, 1954. Complications in the original series of 246 arthroplasties included thrombophlebitis, 12 (5%); thrombophlebitis with pulmonary embolism, 9 (3.7%); miscellaneous, 8 (3%); subluxation, 4 (1.6%); wound sepsis, 3 (1.2%); death, 3 (1.2%); and dislocation, 1 (0.4%).

patients with mold arthroplasties desc
most always different from that whi
felt before the operation. It was rare
pain and was located in the trochanter

riceps regions and described as muscle soreness. It was usually associated with "overdoing," and the patients soon learned how to avoid activities which caused this pain. It was common for a patient who had had the arthroplasty for many years to say that his hip got better with each year.

Walking.—A scale for walking endurance, regardless of the amount of support needed, was used to indicate the development of endurance as follows: grade 1, walks as much as a normal person of the same age and sex; grade 2, walks up to one mile; grade 3, walks up to one-half mile; grade 4, walks only two to three city blocks; grade 5, walks only as necessary (from room to room); and grade 6, unable to walk, leads essentially a bed-and-chair existence.

Figure 3 shows the distribution of walking endurance. Most of these patients were able to walk at least one-half mile in a sustained walk, the poorest being those with unilateral arthroplasty in the presence of bilateral disease. These patients were generally held back by the hip without the arthroplasty. It was found that 18 of the 19 patients with unilateral disease who were at least eight years since operation could walk at least one-half mile, and 18 of the 23 patients with bilateral arthroplasties, at least five years since operation, could walk at least one-half mile. Twenty-four per cent of all patients had unlimited walking endurance.

Support.—The patients were asked to use enough support to keep them from limping and to protect them from muscle fatigue and pain. The use of adequate support allows the patient more comfortable physical activity than is possible without support. As muscle strength and endurance developed we allowed them to diminish the amount of support, but to return to more support if limp or symptoms occurred.[8] After a few months the patients understood this principle and were generally cooperative. Many patients learned to carry a cane long after they had developed a gait with a barely perceptible limp in case they should inadvertently "over-do." Thus, when we say in our charts "cane, part time," we mean that the patient will use the cane out of doors but is not dependent on it. We do not refer to the patient who uses the cane for support out of doors and the furniture indoors. These statements agree with those of Blount[7] and are made to explain the common use of support among our patients. The grading was on a four-point basis, as follows: grade 1, no support; grade 2, cane part time; grade 3, cane full time; and grade 4, crutches.

Of the patients with unilateral hip disease about three-quarters used little or no support. This was not true of patients with bilateral disease; only two patients with bilateral arthroplasties walked without some sort of support for one hip or the other, and most of them used a cane to support one hip. Patients with unilateral arthroplasty in the presence of bilateral disease were about as dependent on support in walking as were those with bilateral arthroplasty. Of the entire group 30% used no support, 34% used a cane part time, 21% used a cane full time, and 15% used crutches.

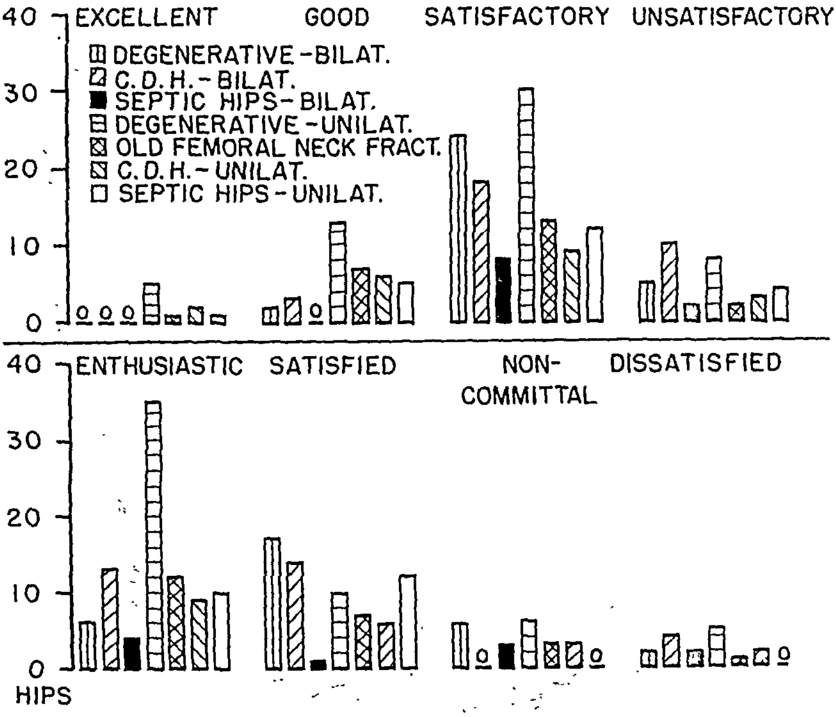

Fig. 2.—Distribution of patients by original diagnosis and two-way evaluation.

General Hip Function.—The following common hip functions were checked on each patient: ability to sit comfortably for one hour, ability to climb stairs foot after foot, ability to tie the shoe on the involved side, ability to squat, and ability to cross the involved leg over the opposite leg.

Only 12 patients out of the entire group were unable to sit comfortably for one hour. This was in contrast to more than two-thirds who had not been able to sit comfortably before operation.

The ability to go up stairs, one foot after the other, is a measure not only of the amount of flexion of the hip but also of its stability. Nearly two-th of the patients with mold arthroplasty were go up stairs one foot after the other, an one-half were able to squat.

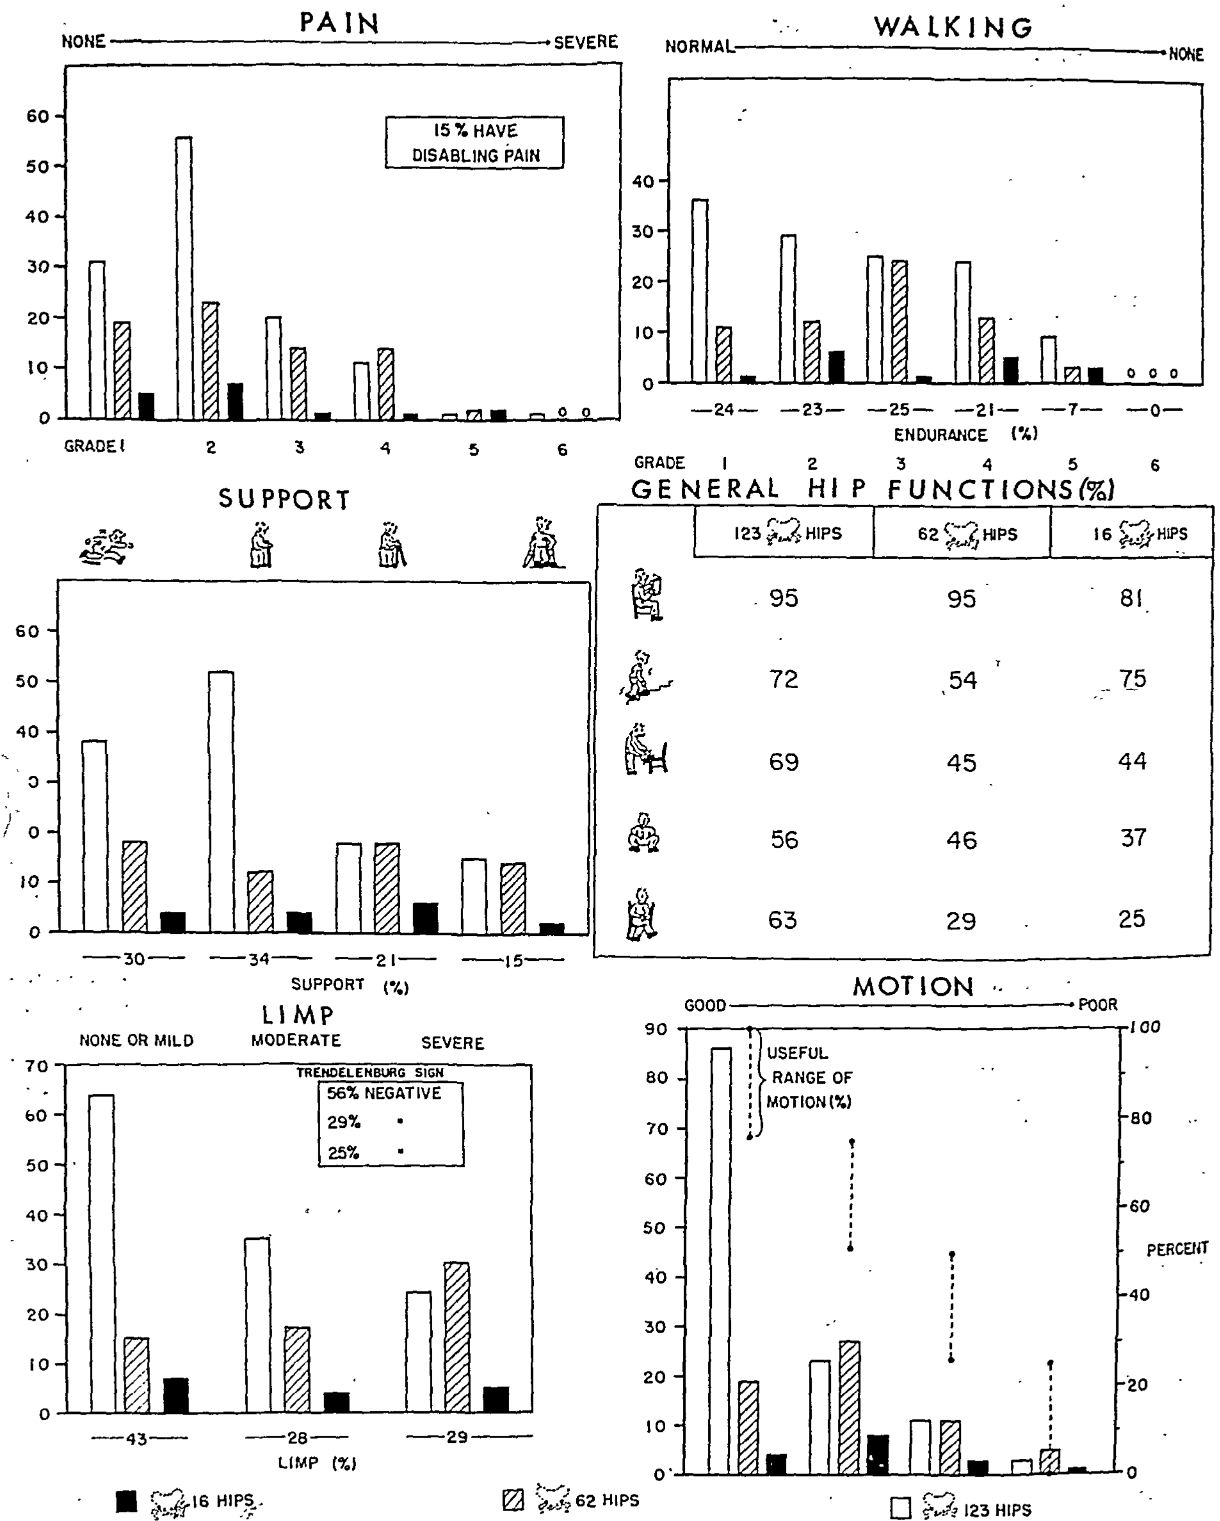

Fig. 3.—Distribution of patients with unilateral repair for unilateral disease (123), bilateral repair for bilateral disease (62), and unilateral repair but bilateral disease (16), by grade of pain, walking endurance, degree of support needed, general hip functions, degree of limp, and useful range of motion. Axis of ordinates: number of hips.

The ability to tie the shoe and to cross the involved leg over the other leg are measures of flexibility. More than one-half of the patients with unilateral hip disease were able to perform these functions, but those with bilateral disease fell short of one-half in the ability to tie the shoes, and only one-quarter could cross the involved leg over the opposite leg.

Limp.—The patients were observed walking with and without support. The limps were classified without support as none, slight, moderate, and severe. The classification refers only to the hip being studied.

Whereas limping was the rule in those patients with bilateral arthroplasty, about one-half of the patients with unilateral hip disease had little or no limp. The disappearance of the Trendelenburg sign is important to the eventual development of a graceful gait without an abductor lurch. It was frequently found that patients with a Trendelenburg-type gait had a negative result of the Trendelenburg test, and the limp could be corrected by simple gait training. Of the 32 patients with bilateral arthroplasties 4 were found to have bilateral absence of the Trendelenburg sign. More than one-half of the patients with unilateral hip disease had no Trendelenburg sign.

Useful Range of Motion.—The range of motion was measured according to the system of Cave and Roberts,[8] and a factor called the "useful range of motion" was determined. The useful range of motion is defined as the sum of motion between 0 degrees of fixed flexion and 90 degrees of further flexion, and between 20 degrees of adduction and 20 degrees of abduction. The useful range of motion is expressed in percentage of the normal useful range of motion, which is 130 degrees. This motion is measured passively and is kept within the above limits to penalize for fixed deformities. Rotation is not included in this arbitrary evaluation because rotation deformities, except for fixed internal rotation, rarely cause serious disability. Adduction deformities are considered to be very serious. The presence of an adduction deformity automatically puts the hip in the unsatisfactory classification. We have elected to use this method, believing that it yields useful information and is much simpler to use than that suggested by Ferguson and Howorth.[9]

We believe that the maintenance of a good passive range of motion is important, because we expect that, with the increased use of the hip under proper management, the muscles have a good chance to develop functional strength through this range. Figure 3 demonstrates that the arthroplastic hips in patients with unilateral disease had much freer motion than those in patients with bilateral disease. Only 10% of patients with unilateral hip disease had less than 50% useful range of motion. Most of those with poor motion in this group had followed an unsatisfactory postoperative program after discharge from the hospital.

Flexion deformity is not a major problem in patients with unilateral hip disease. Every step they take with the uninvolved hip tends to extend the involved hip. The patients were taught to stand with the hip in extension. It is much easier for patients with only one arthroplasty to care for the hip properly than it is for patients with two arthroplasties. Of the patients with a unilateral arthroplasty for unilateral disease only 17% had flexion deformity in excess of 15 degrees.

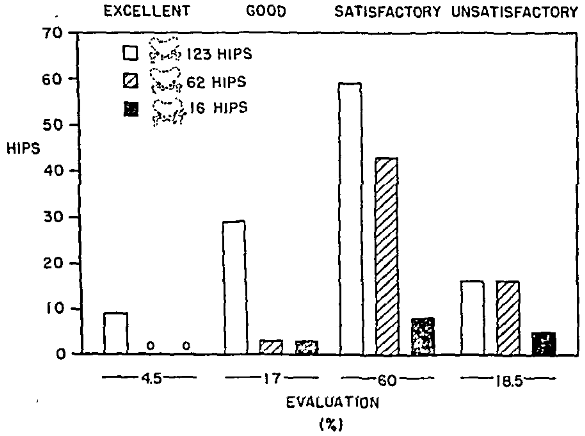
The problem is entirely different in the patients with bilateral hip disease, whether they have bilateral arthroplasty or not. Of these patients 60% were found to have flexion deformities in excess of 15 degrees, with 18% of the hips having more than 35 degrees of permanent flexion. It is believed that this deformity develops because, with weakness in both hips, the patients tend to sit more than they should, and when they stand and walk they prefer the tripod position, leaning forward on their crutches for more stability. It requires constant effort on the part of the patient to overcome these habits. A hip treated with arthroplasty is almost certain to assume the fixed flexion deformity of the opposite hip. In general, despite the high incidence of serious flexion deformities in the hips of patients with bilateral hip disease, these hips had good ranges of motion beyond their flexion deformities. The flexion deformity can be prevented by proper postoperative management.[10]

Only three patients in the entire group developed ankylosis in the involved hip. Of these, two were lost to follow-up examination early in the study and one had had ankylosis of the hip prior to operation as the result of septic arthritis as a child. This patient has had a second operation and is doing very well.

Clinical Evaluation and Patient Reaction

The clinical classification of renovated hips was as follows: Excellent: pain, grade 1 or 2 (little or no pain); walking, grade 1 (walks as far as a normal person of the same age and sex); support, none; limp, none or mild; hip functions, can sit comfortably for at least one hour, climb stairs foot after foot, and tie own shoe; useful range of motion, 75 to 100% without adduction deformity (98-130 degrees). Good: pain, grade 1 or 2 (little or no pain); walking, grade 1 or 2 (can walk at least one mile); support, no more than a cane part time; limp, moderate or better; hip functions, can sit comfortably for at least one hour, climb stairs foot after foot, and tie his own shoe; useful range of motion, 50 to 100% without adduction deformity (65-130 degrees). Satisfactory: pain, grade 4 if improved, or grade 3 or better (tolerable with limited activit improved or no more than mild when walking, disappearing with rest); walking, grade 4 if improved, or grade 3 or better (two to three city blocks if improved or at least one-half mile); support, may use cane or crutches; hip function, can *sit comfortably at least one hour; useful range of* motion, 25 to 100% without adduction deformity (33-130 degrees). Unsatisfactory: anything less than satisfactory.

It is obvious that any of the many factors used in this classification may change a given hip one or more categories. It is not enough for an arthroplasty to give good relief of pain; if this were the case results in more than 80% of the hips in this study would be called excellent. The goal is to establish as near normal function as is possible in each case. In our evaluation of these hips we used normal hip function as the standard as suggested by Hammond and co-workers.[2] This is a very strict measuring stick, but we feel it gives a more readily comprehensible assay of a large group of patients than can be obtained in the use of Judet's amelioration rate[4] or Shepherd's system.[11] In the final analysis, we are interested in how these patients function as compared to the general population. Figure [illegible] shows the comparative results of the three major groups of patients. Of the entire group 4.5% were excellent, 17% were good, 60% were satisfactory, and 18.5% unsatisfactory.



EVALUATION	CO-OPERATIVE (%)	UNCO-OPERATIVE (%)
EXCELLENT	5.5	2
GOOD	22.5	5
SATISFACTORY	56	68.5
UNSATISFACTORY	16	24.5
TOTAL —	144	57 HIPS

Fig. 4.—*Top*, distribution of patients by clinical results. *Bottom*, effect of patients' cooperation on clinical evaluations.

All of the "excellent" hips were found in those patients with unilateral arthroplasty for unilateral *disease, comprising 7.5% of that group. A great* majority of the "good" hips were also found in these patients. Most patients were eliminated from the "excellent" and "good" classifications by limitations of walking endurance and by inability to tie their shoes and climb stairs foot after foot. Obviously, the functional problems are compounded by the presence of disease in both hips, and only a few patients with bilateral arthroplasty could be expected to accomplish anything beyond "satisfactory" function. Most of the patients with hips classified as "satisfactory" far exceeded the minimum requirements for this classification in most components of the analysis. Of these 61% required no more support than a cane part time.

Of the 201 hips examined, 103 were in ward patients and 98 were in private patients. It was obvious from the beginning of the project that the private patients were much better controlled than the ward patients, although the follow-up examinations in both groups were directed by the same surgeons and the outline of management was the *same. As a group, the private patients seemed* to grasp the significance of the follow-up program better than the ward patients. There was a much lower rate of failure to meet follow-up appointments among the private patients. In general, the private patients had less pain, could walk farther, required less support, and had less limp, better stability and mobility, and a lower percentage of unsatisfactory hips. Of the ward patients 22% of the hips were unsatisfactory as compared with 14% of the hips of private patients.

Patient Reaction.—During the interview the patient's reaction to the arthroplasty was carefully reviewed and his reaction classified by the examiner as enthusiastic, satisfied, noncommittal, or dissatisfied. Patient reaction data are summarized in figure 5.

The patient reaction was more favorable than the clinical evaluation (fig. 5, *bottom*). A large percentage of patients with unsatisfactory clinical results were quite pleased with the result, usually because of relief of pain. With a few exceptions, the more pain and disability the patient had before operation the more satisfied he was with the result.

Special Groups

Clinically Satisfactory Results.—There were 120 hips which were classified as satisfactory, excluding the excellent and good hips. Of these 120 hips 90 caused little or no pain, 23 caused pain which was mild when walking and disappeared with rest, and 7 caused pain which was tolerable with limited activity. Twenty-two allowed unlimited walking, 26 allowed walking at least one mile, 41 allowed walking at least one-half mile, 24 allowed walking only two or three city blocks, and in seven patients walking was limited to from one room to another. The last seven hips are included in the satisfactory group because conditions other than the hips were the limiting factors. Twenty-seven of the hips required no support, 46 required a cane part time, 30 a cane full time, and 17 required the use of crutches. Forty-seven of the hips did not exhibit Trendelenburg's sign.

Clinically Unsatisfactory Results.—There were 37 hips classified as unsatisfactory. Of these hips 10 caused little or no pain, 6 caused mild pain when walking which disappeared with rest, 15 caused pain which was tolerable with limited activity, 5 caused pain which was severe with walking and limited activity markedly, and 1 caused severe pain at all times, interfering with sleep. Three of these hips allowed unlimited walking, 3 allowed walking to at least one mile, 7 allowed walking up to one-half mile, 15 allowed walking only two or three city blocks, and 9 allowed walking only from one room to another. Four of these hips required no support, 7 required a cane part time, 12 a cane full time, and 14 required crutches. Of the patients with unsatisfactory results 23 were satisfied or enthusiastic and 14 were either noncommittal or dissatisfied.

Shaft Arthroplasty.—The shaft arthroplasty is performed when there is not sufficient head or neck available for the usual positioning of the mold. In this procedure the proximal end of the femoral shaft is prepared by removing the greater and lesser trochanters and placing the mold on the end of the shaft which is then placed in the new acetabulum. The greater trochanter, with the insertions of the hip abductors, is then transplanted down the lateral aspect of the femoral shaft and the iliopsoas tendon to the anterior aspect of the femoral shaft to reestablish the functional length of these muscles. This procedure results in shortening of the femur. Although the shaft arthroplasty yields a weak hip, its function is remarkably good.[10a] Until good femoral head and neck prostheses were developed, this was almost standard treatment at the Massachusetts General Hospital for nonunion and aseptic necrosis after femoral neck fractures. The prosthesis has now taken its place as the preferred treatment in these conditions. Occasionally a hip reconstruction with the use of a prosthesis becomes complicated by sepsis or by disintegration of the proximal end of the femur, but catastrophe can be converted into a satisfactory result by the use of a shaft arthroplasty with a mold.

Of the 21 patients with unilateral hip disease treated with shaft arthroplasty 17 had little or no pain, six were unlimited in their walking, 5 could walk at least one mile, 3 could walk at least one-half mile, 5 could walk only two to three city blocks, and 2 were able to walk only from one room to another. The two patients who could walk only from one room to another were elderly persons who otherwise probably would have been bedridden. Of these patients 10 required no support in walking, 5 used a cane part time, 5 used a cane full time, and 1 was entirely dependent on crutches. Twelve of the patients had no Trendelenburg sign. Although none of the hips could be classified as excellent, 10 were classified as good, 10 as satisfactory, and only 1 as unsatisfactory.

UNSATISFACTORY	37	16	47	16	21

Fig. 5.—*Top*, distribution of patients by reaction to clinical results. *Bottom*, relation of reaction to clinical evaluation.

Hips Ankylosed by Septic Arthritis.—There were eight patients in the group examined who had an arthroplasty performed for septic arthritis of one hip, resulting in ankylosis in poor position. Of these patients four had little or no pain, three had pain which was mild when walking and disappeared with rest, and one had pain which was tolerable with limited activity. One of the patients was unlimited in walking, three were able to walk at least one mile, two were able to walk at least one-half mile, and one was able to walk only two or three city blocks. One patient required no support in walking, three required a cane part time, three required a cane full time, and one required crutches. Four of the eight patients had no Trendelenburg sign. One of these hips was classified as excellent, six as satisfactory, and one as unsatisfactory. All of the patients were either satisfied or enthusiastic about the results of surgery.

Three of the four patients who exhibited no Trendelenburg sign were in their teens and one was 5 years old at the time of the original ankylosis. The average time between ankylosis and arthroplasty was 24.5 years for the group as a whole and 15.75 years for those with no Trendelenburg sign. All of the patients with a Trendelenburg sign developed ankylosis before the age of 10 years.

Supplementary Surgery.—Of the 237 hips in 194 patients who underwent their first arthroplastic procedure at the Massachusetts General Hospital during the period being studied, 23 have required major supplementary surgery consisting of at least capsulectomy and acetabuloplasty. This group is broken down to 15 (9%) of 169 patients with unilateral arthroplasty; 8 (24%) of 33 patients with bilateral arthroplasty; 15 (15%) of 99 ward patients; and 8 (8.5%) of 95 private patients; for a total of 23 (12%) of 194 patients.

The indications for supplementary surgery were persistent pain, loss of motion, instability, and persistent sepsis. Supplementary operations were performed for pain and/or limitation of motion in 73% of the hips, for subluxation or dislocation in 15%, and for persistent sepsis in 12%. None of the revised hips was rated as excellent, 19% were rated as good, 58% were rated as satisfactory, and 23% were rated as unsatisfactory. This represents a salvage rate of 77%.

Comment

The study of a group of surgical patients by a surgeon who had no hand in the surgery will usually remain unbiased. A cold clinical study cannot tell the whole story. Many other factors enter into the total picture; such things as enthusiasm or indifference, other demands on the patient's time, and his individual characteristics and physical ability all contribute to the end-result. These same things apply to the doctor and his relationship with his patient. This logically sets up a two-way evaluation of the result: the patient's and the surgeon's evaluation. The over-all results of these two systems were the same, although the finer points of the clinical evaluation were more severe. The patients were more generally pleased than the surgeon. This is as it should be. It will keep us working for better results and at the same time build up our confidence by patients' approval.

The factual data in this study have a major weakness in that they cannot reveal the reasons why we have altered a surgical technique and/or the aftercare of these patients. Yet both of these factors, we believe, have made major differences in the total end-result.[12]

Physiological healing of bone, tendon, and muscle must take place before heavy functional use should be expected or tried. This process will take many months in atrophied bone and weak muscle. It is a gradual process, and any attempt to force or hurry the progress of improvement will often be disastrous.

A gradual, gentle program which includes regular exercise and regular rest is essential. Supportive weight-bearing with both crutches is mandatory until there is clinical and roentgenologic evidence of bone healing. The gradual loss of sensitivity in and about the hip with roentgenologic evidence of increasing homogeneous density is a guide to increasing activity. The management of the reconstructed hip joint follows closely that of a fracture of the femur with a little more concern about weight-bearing and a little more time for dense healing. This is necessary because the weight falls on a small surface and the levered forces act on these surfaces.

Summary and Conclusions

The following conclusions can be drawn from our study: 1. The surgical hazards of mold arthroplasty are not great. 2. Relief of disabling pain may be expected in 85% of patients, with complete relief of pain in 27%. 3. Unlimited walking may be expected in 24%, walking without support in 30%, with a cane part or full time in 55%, and with crutches in 15%. 4. A wide useful range of motion may be expected in patients with unilateral disease, and a limited useful range of motion may be expected in those with bilateral disease. 5. A satisfactory or better result may be expected in 81.5% of patients, good to excellent result in 28% of those who are able to follow the postoperative program, and good to excellent results in 7% who are unable to follow the postoperative program. The group of patients unable to follow the postoperative program may expect a one-third greater chance of obtaining an unsatisfactory result. 6. There is no constant correlation between the clinical evaluation of the result of surgery and the patients' own evaluation. 7. Supplementary surgery may be required in 12% of patients, with an expected salvage rate of 77%.

STUDY OF SURGICALLY EXCISED PULMONARY GRANULOMAS

Edward L. Segal, M.D., Grier F. Starr, M.D.
and
Lyle A. Weed, M.D., Rochester, Minn.

The cause of the majority of surgically excised pulmonary granulomas has not been determined, even with extensive bacteriological studies. However, through application of Gomori's methenamine-silver nitrate stain (GMS) to 138 such surgically excised lesions over a two-and-a-half-year period, it was possible to identify "structures" resembling Histoplasma capsulatum or Coccidioides immitis in 55.9%. Despite extensive efforts, it was not possible to obtain fungus growths from these structures, which are thought to be nonviable fungi that have lost their ordinary stainability. With the GMS stain, fungi can be found in tissue sections more rapidly and under lower magnification than by other staining methods.

The cause of the majority of surgically excised pulmonary granulomas has not been determined, even with extensive bacteriological studies. In 1951, Good and associates[1] found it possible to identify a causative agent in only 21 of 65 surgically excised pulmonary granulomas with use of standard bacteriological and histological methods. In general, granulomas are excised from the lung because a diagnosis of pulmonary malignant tumor cannot be excluded; approximately one-third of solitary masses excised from the lungs are granulomas.[2] For the past two and one-half years, Gomori's methenamine–silver nitrate stain[3] (GMS) has been applied at the Mayo Clinic to these surgically excised pulmonary granulomas in addition to the routine bacteriological and histological methods; this study was undertaken in an attempt to evaluate the results obtained with the GMS stain as an aid in determining the cause of these granulomas.

Methods and Materials

Methods.—Since September, 1946, all surgically excised pulmonary granulomas have been examined at the clinic by the following procedure: If the surgeon suspects that the pulmonary mass he is resecting is a granuloma, he bisects the specimen and, utilizing aseptic techniques, places half of the specimen in a sterile container for bacteriological studies and sends the other half to the surgical pathology laboratory for identification by examination of fresh frozen sections (with use of Terry's modified polychrome methylene blue).

If the surgical specimen contains a granuloma, the half in the sterile container is ground aseptically in a mortar and pestle with 60-mesh aluminum oxide (alundum), and a 20% suspension is made in broth. This suspension is then inoculated by the massive-inoculation technique, that is, a few drops of the suspension are placed on the medium and distrib-

uted with a glass rod; these mediums are used: hormone blood agar[4] at 37 C, 30 C, and, in 10% carbon dioxide solution, 37 C (all in duplicate); chocolate agar in 10% carbon dioxide solution at 37 C; thioglycollate broth or brain broth at 37 C; Lowenstein-Jensen medium at 37 C (in duplicate); Petragnani's medium at 37 C (in duplicate); and subcutaneous and intraperitoneal inoculation into two guinea pigs.

The organisms most frequently encountered as the causative agents of pulmonary granulomas are the pathogenic deep fungi, Mycobacterium tuberculosis, Brucella, Nocardia, Actinomyces, and Hemophilus influenzae. Routine cultures are observed for three weeks, cultures for Myco. tuberculosis for a maximum of eight weeks, and inoculated guinea pigs for eight weeks. Depending on the results of these cultures and animal inoculations, special stains are used and appropriate subcultures made.

The other half of the granuloma, which had been utilized for the frozen section, is embedded in paraffin, sectioned, and stained as follows: routine stain, hematoxylin and eosin; acid-fast bacilli, night-blue stain[5] counterstained with safranine; and fungi, periodic acid–Schiff stain (PAS) used from 1952 to 1955 and GMS[3] from 1956 to the present. These slides are available by noon of the following day; if "structures" resembling organisms are seen histologically, the bacteriology laboratory is notified so that appropriate extra mediums may be inoculated if necessary.

Materials.—From September, 1946, through June, 1958, a total of 603 surgically resected pulmonary granulomas have been studied by means of the routine procedure outlined above. None of the 465 granulomas excised before 1956 were stained by the GMS technique. There were 138 granulomas excised during the two-and-one-half-year period from January, 1956, through June, 1958; all these granulomas were stained by the GMS technique.

Mainly on the basis of gross appearance, pulmonary granulomas can be classified into one of three main morphologic types: (1) tuberculoma-like—discrete, solitary, well-circumscribed, nodular, caseous, nonexcavating, granulomatous lesions; (2) infiltrative—diffuse lesions with multiple foci of caseous and noncaseous, nonexcavating, granulomatous reactions; and (3) excavating—excavating caseous lesions with granulomatous reactions. Of the 138 granulomas stained by the GMS technique, 92 were of the tuberculoma-like type, 29 were of the infiltrative type, and 17 were of the excavating type.

For purposes of discussion, the 138 GMS-stained pulmonary granulomas were placed into three groups based on the bacteriological and histological findings in each granuloma. Group A, positive culture, included those granulomas in which the causative organisms were isolated by culture. Group B, negative culture and positive histopathology, included those granulomas in which "structures" resembling organisms were found by histological methods but all attempts to culture these structures were unsuccessful; also included in this group were lipoid granulomas and eosinophilic granulomas. Group C, negative culture and negative histopathology, included those granulomas which were culturally sterile and in which no structures resembling organisms were observed histologically.

Observations

The results of study of the 138 GMS-stained pulmonary granulomas are summarized in table 1. Results of culture in approximately one-fourth (23.8%) of the granulomas were positive (group A). More than half (55.9%) of the granulomas were found to contain structures that resembled organisms on microscopic examination of the GMS-stained sections; all attempts to culture these structures were unsuccessful (group B). Approximately one-fifth

(18.9%) of the granulomas were culturally sterile and contained no structures resembling organisms on histological examination (group C).

Of the 92 tuberculoma-like pulmonary granulomas, only 5 gave positive results on culture (group A), while 80.4% of the granulomas contained microscopic structures resembling organisms that could not be grown on culture mediums (group B). These structures, observed in the GMS-stained sections, resembled Histoplasma capsulatum (fig. 1*a* and *b*) in 72.8% and Coccidioides immitis (fig. 2) in 7.6% of these tuberculoma-like granulomas. These structures resembling organisms were found scattered in the central caseous debris of the pulmonary granulomas. With the PAS stain (fig. 1*c*), these structures appeared to be distorted forms of H. capsulatum; many of them had lost their central, purplish-red mass. In one granuloma in group B, acid-fast bacilli were observed in the section stained by the night-blue technique but all cultures of this lesion gave negative results. Also included in this group were one lipoid granuloma and one eosinophilic granuloma. Only 13% of the tuberculoma-like pulmonary granulomas gave negative cultural and histological results (group C).

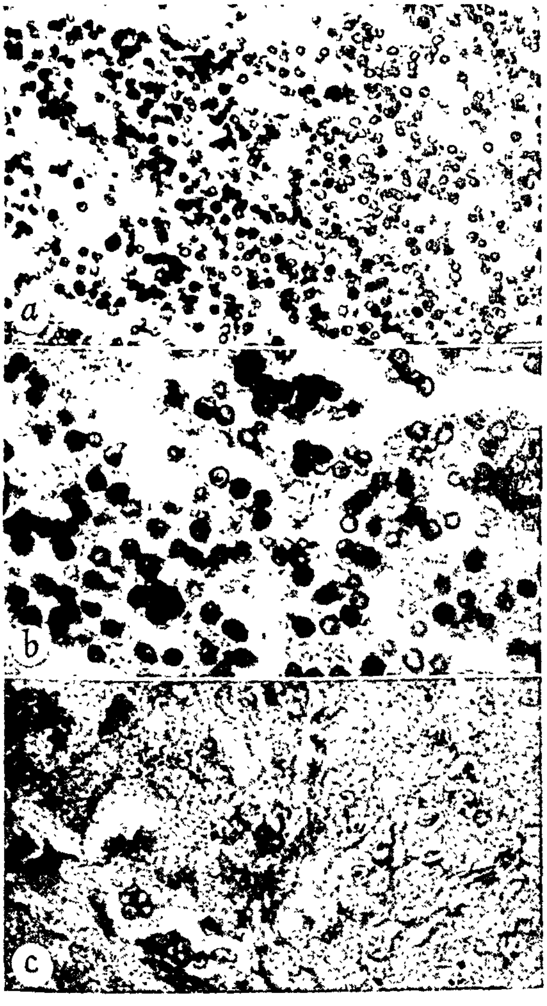

Fig. 1.—Structures histologically resembling H. capsulatum in culturally sterile pulmonary granuloma. *a*, GMS, ×480; *b*, GMS, ×970; *c*, PAS, ×970.

Of the 29 infiltrative pulmonary granulomas, more than half (51.9%) gave culturally positive results (group A). Only one pulmonary granuloma of the infiltrative type contained structures histologically resembling H. capsulatum in the GMS-stained section and gave negative results on culture (group B). Sputum culture from the patient from whom this pulmonary granuloma was excised had given positive results for H. capsulatum approximately nine months prior to excision of the pulmonary lesion. After one month of rest in bed, his sputum no longer had shown evidence of H. capsulatum. Five months before operation, he had been treated for 10 weeks with amphotericin B. The lesion removed at operation was diffuse and was classified as an infiltrative pulmonary granuloma.

Of the 17 excavating pulmonary granulomas, more than three-fourths (76.5%) gave culturally positive results (group A). Fungi were not seen in any of the GMS-stained sections of these granulomas.

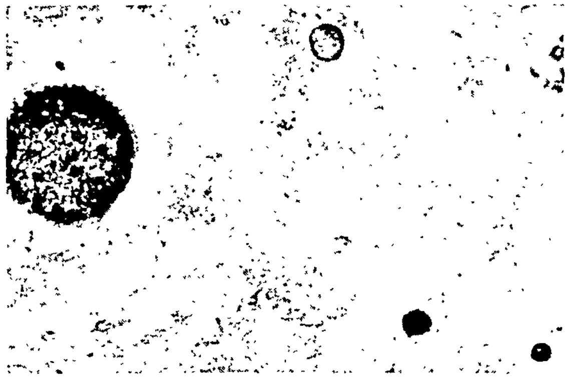

Fig. 2.—Structures histologically resembling C. immitis in a culturally sterile pulmonary granuloma. Endosporulating spherule on left, developing spores on right (GMS, ×970).

Only 1 of the 69 granulomas that contained structures resembling H. capsulatum on GMS-stained sections gave positive results on culture. This lesion is illustrated in figure 3. The structures in this lesion were present in intact macrophages instead of being scattered in the caseous debris. C. immitis was isolated by bacteriological methods from 5 of the 12 lesions that contained structures resembling this fungus.

Data comparing the pulmonary granulomas excised before use of the GMS technique with those excised subsequently are summarized in table 2. The percentage of granulomas in the positive culture group (group A) decreased from 36.8 to 23.8. The percentage of granulomas with negative culture and positive histopathology (group B) increased approximately 10 times (5.8 to 57.3%). In only one culturally sterile granuloma in the group in which the GMS stain was not applied were structures found that histologically resembled H. capsulatum, and in only one culturally sterile granuloma in this same group were structures found that histologically resembled C. immitis; the structures in both of these granulomas were found in sections stained by the PAS technique. The percentage of granulomas with negative culture and negative histopathology (group C) decreased approximately threefold (57.4 to 18.9%).

Clinical Data and Pathology

Clinical Data.—As already noted, 68 of this series of 138 patients had pulmonary granulomas that were culturally sterile but in which GMS-stained sections showed structures morphologically resembling H. capsulatum. Table 3 lists the resident states and countries of these 68 patients and compares the percentage of them residing in these states and countries with the percentage of all Mayo Clinic patients residing in these same states or countries. Figure 4 indicates the geographical distribution of cutaneous sensitivity to histoplasmin (percentage of positive reactors) in the United States, based on the analysis of Furcolow,[6] as well as the percentage of the 68 patients residing in each state.

Approximately 45% of these patients came to the clinic specifically for evaluation of a solitary nodule or "coin" lesion that had been found on a thoracic roentgenogram taken either as part of a routine physical examination or during a survey by a mobile unit; in the remaining 55% of the patients, the pulmonary lesion was first discovered in the thoracic roentgenogram taken as part of the routine examination at the clinic. These patients had no pulmonary symptoms or physical signs that could be related to an infectious process at the time of their examinations. Approximately 90% of the patients could not recall any definite episodes in their histories when they might have been infected with H. capsulatum; about 10% of the patients did recall an episode of malaise and fever lasting from 1 to 10 days that was sometimes accompanied by cough or thoracic pain. In general, these episodes had been diagnosed as an infection of the upper part of the respiratory tract, influenza, or atypical pneumonia. The thoracic roentgenograms were described as showing a solitary, nodular, sharply circumscribed lesion varying from 1 to 3 cm. in diameter. *Calcium* was recognized in these routine roentgenograms in only 2 of the 68 cases. Tomography was performed in 54 of the 68 cases; calcification was found in five lesions, and questionable calcification was found in four additional lesions. The results of intracutaneous

tests with histoplasmin, tuberculin, coccidioidin, and blastomycin are summarized in tables 4 and 5. In only 24 of the 68 cases had the histoplasmin skin test been applied; the results were positive in 22 of the cases and negative in 2.

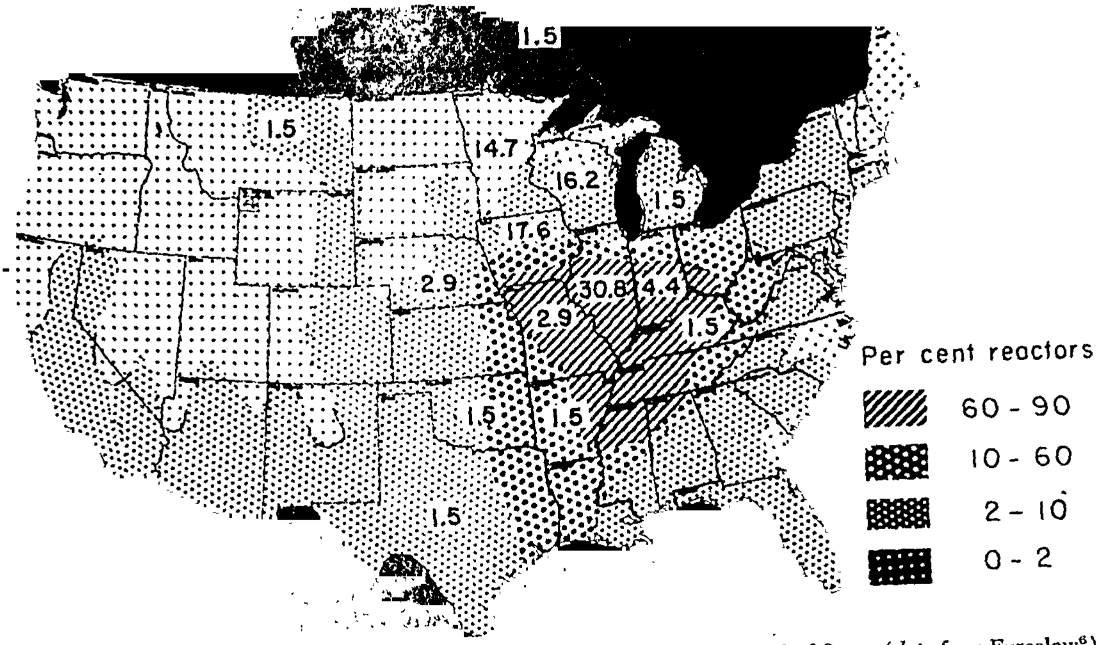

Fig. 4.—Geographic distribution of cutaneous sensitivity to histoplasmin in United States (data from Furcolow[6]). Numbers indicate percentages from each state of our 68 patients with culturally sterile pulmonary granulomas containing structures resembling H. capsulatum.

Seven of the 138 patients had pulmonary granulomas that gave negative results on culture but in which the GMS-stained sections showed organisms morphologically resembling C. immitis. Six of these patients had resided or traveled in California, and the seventh patient's residence was in Arizona. The chief complaint of three of these patients was a solitary pulmonary nodule that had been found on a thoracic roentgenogram taken in their home town; in the other four patients, the lesion was first discovered in the thoracic roentgenogram taken as part of the routine examination at the clinic. These patients did not have any pulmonary symptoms or physical signs that could be related to an infectious process at the time of their examinations. Five of the patients had been asymptomatic. In 1952, one patient had been treated with streptomycin for "desert fever." In 1955, another patient had been hospitalized in a sanatorium with chills, fever, and thoracic pain but was released when tuberculosis had been excluded. The lesions observed in the thoracic roentgenograms in these seven patients were similar to those seen in the 68 patients discussed in the preceding paragraph. Calcification was not observed in the routine roentgenograms, and tomography, performed in four of the seven cases, also failed to reveal any calcification. In two of the patients, three intracutaneous tests (coccidioidin, histoplasmin, and tuberculin) had been utilized and all three gave positive results. In an additional two patients, only the tuberculin skin test had been used; it gave positive results in one patient and negative results in the other. Intracutaneous tests were not given to the remaining three patients.

Pathology.—The culturally sterile pulmonary lesions observed in the 68 granulomas containing structures histologically resembling H. capsulatum and in the seven granulomas containing structures histologically resembling C. immitis were identical on gross and microscopic examination except for the presence of the different structures observed in the

GMS-stained sections. In addition, these lesions could not be differentiated from the "tuberculomas" observed in infections with Myco. tuberculosis other than by identifying the offending organisms (fig. 5). The lesions were solitary, circumscribed, and grayish-white, and they varied from 1 to 3 cm. in diameter, with a central caseous zone (sometimes containing flecks of calcium) and peripheral concentric laminations. The consistency varied from semifluctuant to hard and rubbery. These 75 lesions were all grossly and microscopically identical and were characteristic of tuberculoma-like granulomas, with the exception of the one lesion that was of the infiltrative type.

Additional Studies

In a further attempt to evaluate the effectiveness of the GMS stain for demonstrating fungi in tissue, sections of selected granulomas excised prior to January, 1956, were stained by the GMS technique. Application of this stain to the 65 granulomas studied by Good and associates [1] revealed the presence of structures resembling H. capsulatum in 20 of the 44 previously indeterminate lesions and structures resembling C. immitis in two of the previously indeterminate lesions. Thus, with the GMS stain, structures resembling organisms were found in 50% of the previously indeterminate, culturally sterile pulmonary granulomas.

In 1954, Starr and co-workers [7] carried out two series of studies in an attempt to evaluate the effectiveness of the PAS stain for demonstrating fungi in tissue. The first series consisted of 50 culturally sterile pulmonary granulomas excised from 1946 through 1953; 22 of these lesions were tuberculoma-like, 21 were infiltrating in type, and seven were of the excavating type. No organisms were found by routine staining with hematoxylin and eosin. The PAS stain revealed the presence of structures histologically resembling H. capsulatum in only 1 of these 50 granulomas, and this lesion was tuberculoma-like. In many of the PAS-stained sections of the granulomas, Starr and associates [7] observed fine red rings surrounding a clear zone without any central purplish-red mass but they would not make a diagnosis of structures resembling H. capsulatum unless such a mass was present. As part of the present study, application of the GMS stain revealed the presence of structures resembling organisms in 16 of these 50 granulomas; these structures were found only in the tuberculoma-like granulomas. In 15 of the granulomas, structures histologically resembling H. capsulatum were observed; structures histologically resembling C. immitis were noted in one granuloma.

The second series studied during the same period by Starr and associates [7] consisted of 61 lesions (including other lesions in addition to pulmonary granulomas) that were culturally positive for pathogenic fungi. Structures resembling fungi had been observed previously in sections stained with hematoxylin and eosin and occasionally by the Brown-Breen-Gram, Stoughton, or Best-Bodian method in 30 of these 61 lesions. The PAS stain disclosed structures believed to be fungi in 21 additional lesions. Application of the GMS stain as part of the present study revealed structures morphologically consistent with fungi in six more lesions. Therefore, structures resembling organisms have not been found histologically with any of the staining methods in only four of these 61 culturally positive lesions (table 6).

Comment

For demonstration of acid-fast bacilli in sections of tissue, we prefer the night-blue stain with safranine counterstain to the more commonly used Ziehl-Neelsen stain, since we found that blue-stained acid-fast bacilli are much easier to see than red-stained acid-fast bacilli. Hallberg [5] discussed the many advantages of the night-blue stain in comparison to other acid-fast staining methods.

Grocott [3a] first suggested using Gomori's methenamine-silver nitrate stain for the demonstration of fungi in tissue. Zimmerman [8] mentioned the various advantages of this technique as compared to methods with other stains for fungi. Since the GMS method affords such a sharp contrast between the fungi, which are stained intensely black, and the background, which is almost colorless, it is possible to find fungi more rapidly and under lower magnification than with other staining methods. Structures believed to be fungi frequently can be demonstrated with the GMS technique when they cannot be found with other staining methods (fig. 6). It is pertinent to emphasize that these organisms are found in the central caseous debris of the granuloma; consequently, it is important that sections be taken to include this central caseous zone. These culturally sterile structures that are only demonstrated by special histological methods are thought to be nonviable fungi that have lost their stainability by ordinary methods.[8]

In the tuberculoma-like type of pulmonary granulomas, which at one time were thought to be pathognomonic of infection with the tubercle bacillus, Myco. tuberculosis was cultured in only 2.2% of lesions; in an additional 1.1% of these granulomas, acid-fast bacilli were observed microscopically but could not be cultured. However, structures resembling H. capsulatum were observed in 72.8% of these tuberculoma-like pulmonary granulomas; in an additional 7.6% of these lesions, structures resembling C. immitis were noted. The tuberculoma-like lesion is assumed to be the healing or healed phase of a pulmonary infection.

Current literature indicates some trend toward the view that improved staining methods can replace microbiological techniques. However, special stains are capable of demonstrating only a few of the specific pathogens, whereas the problem in a granulomatous lesion is to demonstrate one of a wide variety of causative agents. Multiple organisms occasionally are isolated from a single granuloma. Obviously, large numbers of infections by the tubercle bacilli or brucellar organisms would go undiagnosed if resort to cultural methods were abandoned. Furthermore, even when a fungus can be demonstrated histologically it is often difficult, if not impossible, to identify the genus with certainty by histological examination alone. With the existence of small forms of Blastomyces and large forms of Histoplasma, one might question the validity of any purely morphologic identification of either of these organisms in tissue. On occasion, Blastomyces, Cryptococcus, and Coccidioides have been confused with one another by the surgical pathologist when he observes these organisms in tissues removed at operation. Another pitfall inherent in morphologic methods is the presence of artifacts that may closely simulate certain pathogenic fungi. Finally, in many granulomas, cultures have revealed the presence of a causative organism that had not been observed in sections of tissue stained by multiple special techniques.

Summary and Conclusions

More than half (55.9%) of a series of 138 surgically excised pulmonary granulomas studied at the Mayo Clinic during a two-and-one-half-year period contained "structures" histologically resembling Histoplasma capsulatum or Coccidioides immitis when stained by Gomori's methenamine–silver nitrate (GMS) technique. Extensive efforts to obtain growth of fungi from these structures were unsuccessful. These culturally sterile structures are thought to be nonviable fungi that have lost their stainability by ordinary staining methods.

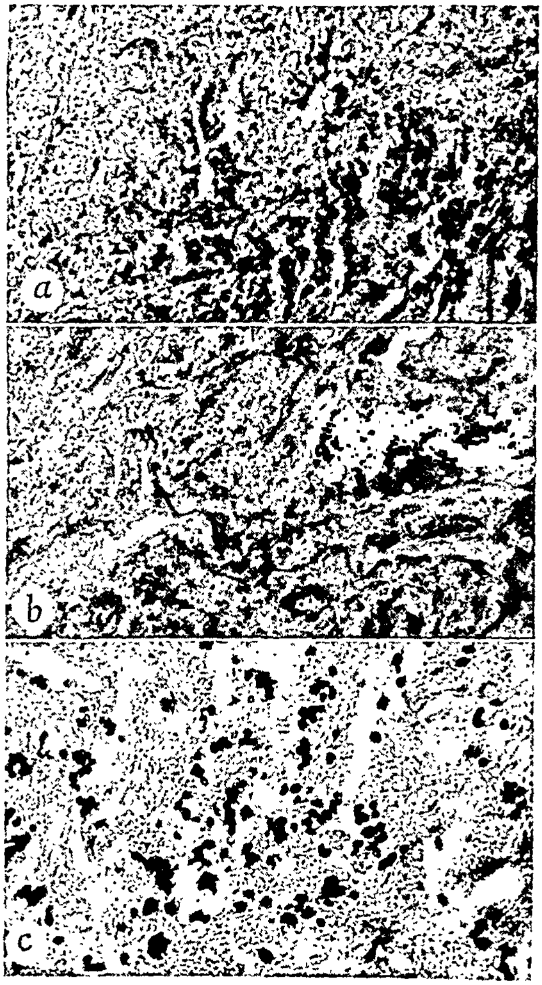

Fig. 6.—Consecutive sections of same area in caseous center of culturally sterile pulmonary granuloma. *a*, hematoxylin and eosin, ×480; *b*, PAS, ×480; *c*, GMS, ×480.

With the GMS stain, fungi can be found in sections of tissue more rapidly and under lower magnification than they can by means of other staining methods. Fungi can be demonstrated frequently with the GMS technique when they cannot be found with other staining methods. Staining methods cannot replace cultural methods; rather, the two methods are supplementary.

VASCULAR ACCIDENTS TO THE BRAIN STEM ASSOCIATED WITH NECK MANIPULATION

David Green, M.B.
and
Robert J. Joynt, M.D., Iowa City

A woman, aged 31, had nausea, vomiting, slurred speech, and diplopia after vigorous manipulation of the neck during chiropractic treatment. There was weakness of the left arm and leg and decreased sensation for touch and pallesthesia over the left half of the body, including the face. The patient's underlying disease was believed to be multiple sclerosis, but the acute episode represented a brain-stem vascular accident secondary to manipulation of the neck. A man, aged 55, had a similar treatment twice. Signs and symptoms became worse with each manipulation. Examination revealed Horner's syndrome on the left side, paralysis of the left vocal cord, and diminished sensation of pain and temperature over the right half of the body. Manipulation of the neck can significantly narrow the lumen of the vertebral artery, and susceptibility to such accidents may depend on an abnormal vascular supply to the basilar arterial system.

Vascular accidents involving the brain stem after vigorous manipulation of the neck have been reported in the past.[1] The mechanism underlying such a catastrophic event was first suggested by De Kleyn and Nieuwenhuyse[2] in a study conducted on autopsy material. They found that extension of the neck and turning the chin to one side severely compromised the circulation through the opposite vertebral artery. Tatlow and Bammer[3] confirmed these findings and supplied postmortem angiographic evidence showing narrowing of the vertebral artery at the atlanto-occipital joint during extension and rotation of the head.

We have recently encountered two examples of this disorder. They are unusual in that the first patient had an underlying neurological disease and had the acute vascular signs engrafted on this. In the second patient, the signs and symptoms progressed successively with each manipulation. Also, the second patient reported pallesthesia (sensation experienced at a point remote from that stimulated), which is infrequently seen with brain-stem lesions.[4]

Report of Cases

Case 1.—A woman, aged 31, was admitted to the University Hospital on June 31, 1957. There was a 10-year history of intermittent diplopia and blurring of vision, with a tentative diagnosis of multiple sclerosis. One week prior to admission, she had a chiropractic adjustment for abdominal distention. Immediately after vigorous manipulation of her neck, she became violently dizzy, vomited, and lost power and sensation in the left arm and leg. Nausea and vomiting persisted for two days along with slurred speech and diplopia.

From the Department of Neurology, State University of Iowa.

On her initial examination one week after the onset, there was weakness and clumsiness of the left arm and leg and decreased sensation for touch, pain, and pallesthesia over the left half of the body, including the face. The Romberg sign was present, nystagmus was noted on left and right lateral gaze, and a Babinski toe sign was present on the left. Results of laboratory studies were normal except for a first-zone rise in the spinal fluid colloidal gold curve. Roentgenograms of the cervical vertebrae, including views of the odontoid process, were normal. Over the next few months, there was almost complete recovery of the strength and sensation in the left arm and leg. The subsequent course of the condition made us feel that the patient's underlying disease was multiple sclerosis but that the acute episode represented a brain-stem vascular accident secondary to manipulation of the neck.

Case 2.—A man, aged 55, was admitted to the Veterans Administration hospital on Aug. 2, 1957. He had sought chiropractic treatment two weeks before for a "strained back and stiff neck." He had been placed on his stomach and his head was rotated to the right and left until his neck "popped." One-half hour after the treatment, he staggered when attempting to walk and could not place his right leg properly. The next morning, the right arm was numb. The following day, he had a similar adjustment, and after this his whole right side was insensitive to pain and he could not discriminate temperature changes, but he maintained the sensation of touch. The right side of the forehead was also numb, the left side of the face did not sweat, and his voice was hoarse.

His admission examination revealed Horner's syndrome on the left, peripheral-type weakness of the left side of the face, deviation of the palate to the right, paralysis of the left vocal cord, weakness of the right arm and leg, diminished pain and temperature (but not touch) over the right half of the body, and slight hypalgesia and hypesthesia of the right side of the forehead. When the right side of his chest was touched, he felt a lightning-like sensation at a similar spot on the left side. Laboratory examinations were normal except for a slightly elevated blood sugar level. Roentgenograms of the cervical vertebrae were interpreted as showing osteoarthritis with lipping of the vertebral bodies. The findings did not change during his hospitalization.

Comment

As it can be readily demonstrated that manipulation of the neck can significantly narrow the lumen of the vertebral artery,[3] it is unusual that only two such cases have been seen in recent years. The chiropractic method was started in Iowa, being introduced near the turn of the century. It is exceptional to interview a patient on the neurological service who has not at some time had one or several neck manipulations. The rarity of vascular accidents, therefore, must stem from one or more of the following conditions being present in the affected cases: 1. The manipulation is unusually violent. 2. The bony structures in apposition to the vertebral arteries must be abnormal by virtue of congenital or degenerative changes. 3. There is underlying vascular disease such as atherosclerosis. 4. There is an abnormal vascular pattern, such as one vertebral artery or one effective vertebral artery which constitutes the major blood flow into the basilar system.

Judging from the vivid descriptions of a typical adjustment, it would seem that there is no paucity of vigorous neck manipulations. Thus, this is probably not a significant factor. Roentgenograms of the cervical vertebrae for the two patients reported on here and for most of the other cases mentioned in the literature have been normal or, at most, showed some osteoarthritis. This does not rule out some subtle change at the atlanto-occipital region, but it is unlikely. The ages (32, 35, 35, 37, 41, 28, 31, and 55) of the patients reported on here and in the literature fell mainly in the fourth decade, so that the presence of advanced atherosclerosis is probably not a determinant. The last possibility, an abnormal vascular pattern, was suggested by De Kleyn and Nieuwenhuyse[2] to account for dizziness and nystagmus in some of their patients when the head was placed in certain positions in relation to the trunk. They found that occasionally one vertebral artery was much larger and reasoned that occlusion of this would embarrass the blood supply of the brain stem. This last explanation seems most likely to account for the reported complication and also for the rarity of brain-stem vascular accidents after manipulations in a population which is overly exposed to such treatment.

Summary

Two patients developed symptoms and signs suggestive of brain-stem vascular accidents after chiropractic manipulation. Other investigators have shown that the vertebral arteries may be compressed during such manipulations. The rarity of this occurrence is ascribed to the fact that the susceptible patient may have an abnormal vascular supply to the basilar arterial system.

INTRADERMAL IMMUNIZATION AGAINST ASIAN INFLUENZA IN CHILDREN

Robert C. Rendtorff, M.D., D.Sc., Lillie C. Walker, M.D., Ph.D., M. Eloise Rowland, Ph.D.
and
Henry Packer, M.D., Memphis, Tenn.

The effectiveness of intradermally injected vaccine against Asian influenza was studied in an orphanage in Memphis, Tenn., with 168 children between the ages of 1 and 17 years. A single lot of monovalent Asian strain type A influenza vaccine containing 200 chick cell agglutination units per milliliter was used throughout the study. The outbreak of influenza in the orphanage began on the same day as in the city of Memphis. Four cases occurred before the first injection, 17 between the first and second, and 5 after the second. The outbreak in the orphanage had substantially ceased before the citywide epidemic had reached its peak. Comparison of the hemagglutination-inhibition titers of serum samples obtained before and after the injections, with a consideration of the time relation of the cases among the different age groups in the orphanage, indicated that the vaccine was effective when given intradermally.

Vaccination has proved to be the only effective method of control against influenza. Because of the possibility of sudden antigenic changes in the virus and the greater effectiveness of a homologous vaccine against the current strain, there may not be time, in the face of an epidemic caused by a new variant of the virus, to prepare sufficient vaccine to protect large population groups. Under such circumstances more persons could be immunized by the intradermal route, which requires less vaccine, if this is proved to be as effective as the conventional subcutaneous route. Whether or not the intradermal route is an effective method of immunization for adults has not been definitely established. However, this method has been a recommended procedure for young children [1] and deserves further study for reasons mentioned above.

During the 1957 Asian influenza outbreak in Memphis, Tenn., we were requested to vaccinate the children of an orphanage. This afforded an opportunity to observe the effectiveness of Asian influenza vaccine given intradermally in the face of an epidemic, and this paper summarizes our experiences.

Materials and Methods

Population.—This study was conducted in an orphanage with 168 children between the ages of 1 and 17 years. Infants under 1 year were not included in the study; however, those from 6 months to 1 year of age were immunized. The orphanage separated the children by age groups for convenience of their care. Two groups of preschool-aged children of mixed sexes, those between 1 and 3 years of age and those between 3 and 6 years of age, were located in a separate building. These had separate dining rooms and play rooms, and they slept, on different floors, in rooms containing two to three beds. The youngest group was supervised by a registered nurse. The girls of the oldest age group (10-17 years) helped to bathe and dress the younger children each evening, which resulted in daily mixing between these age groups.

The school-aged children were divided into two groups, aged 6-10 and 10-17 years, who lived in an area separated from the younger age groups. These two groups of older children took meals in a communal dining room. The dormitories were large,

---

From the Division of Preventive Medicine, University of Tennessee College of Medicine.

unpartitioned rooms, one each for boys and girls of the 6-10-year group and one each for boys and girls of the 10-17-year group. The children of the first four grades (6-10 years) attended school on the premises of the orphanage. The older children went to public or parochial schools in the city.

There were two visiting Sundays a month and much interval visiting to the institution. Thus the children, particularly the older children, had considerable contact with people outside of the orphanage.

Vaccination.—The first dose of vaccine was given to the children between Oct. 18 and 22. A single lot (035331-B) of monovalent Asian strain type A influenza vaccine containing 200 chick cell agglutination (CCA) units per cubic centimeter was used throughout the study. One-tenth cubic centimeter was given intradermally on the flexor surface of the forearm, and this dose was repeated in seven or eight days.

Only 13 of the total population of 168 children failed to receive the two doses of vaccine. Of these, four had the original cases of illness in the 10-17-year age group, becoming ill Oct. 15-16; five were in children in the older age groups who became ill after their first dose of vaccine and were not given the second dose; and four were children who escaped vaccination due to circumstances beyond control. All of the orphanage personnel, except one maid, were given similar vaccine from another source at the same time the children were vaccinated. Children newly admitted to the orphanage were vaccinated as they arrived.

Clinical Follow-up Study.—Clinical observations were made daily by the pediatrician (L. C. W.) during the period of study, which was from Oct. 15, 1957, to Nov. 25, 1957, although clinical observation was carried out beyond this period. In addition to noting evidences of clinical disease, attention was given to both systemic and local reactions to the vaccine. The local reactions were recorded after 24 hours, again at 3 or 4 days, at 7 days, and, finally, at 30 days after vaccination.

Laboratory Methods.—Virus isolations were attempted in some cases of clinical illness. Throat washings were inoculated into the amniotic sac of 10-to-11-day-old hen eggs, and viruses isolated were typed for final identification by the laboratory of the Tennessee Department of Public Health.

Blood specimens were taken immediately prior to vaccination and again one month later. Serums were separated within 24 hours and stored at −20 C until tested. Hemagglutination-inhibition (HI) tests were performed on these serums by the standard reference technique with chicken red blood cells.[2] Asian influenza virus strain A/Japan/305/57 in the seventh pure-line egg passage was used in these tests.

Results

The first cases of illness suggesting influenza were observed on Oct. 15 and 16, 1957, in four girls in the 10-17-year age group. The onset was sudden, with rise in temperature to 102 F (38.9 C), headache, malaise, myalgia, and cough. They were not observed to have coryza or red throats. No virus isolations were attempted on these children; however, serologic findings were indicative of Asian influenza, showing at least a fourfold rise in the HI titer. These initial cases occurring in the orphanage corresponded in occurrence to a widespread outbreak in the city of Memphis. Unpublished data on absenteeism among school children collected by Dr. Nobel W. Guthrie of the Memphis-Shelby County Health Department indicate that this community outbreak of influenza began about Oct. 14-15 and reached a peak about Nov. 4, 1957.

Vaccinations were begun on the younger children in the orphanage on Oct. 18, after the occurrence of the above cases, and all of the other children and personnel received their first immunization by Oct. 22. The second doses of vaccine were given between Oct. 25 and 30. Thus, the entire orphanage population, with the minor exceptions noted previously, was protected by vaccination, but not until after clinical cases of influenza had appeared in the older group and in the community. Table 1 shows the dates of vaccination and the occurrence of clinical cases of influenza among children in each age group.

Seventeen clinical cases of influenza occurred between the first and second doses of vaccine. These were in 12 girls and 1 boy in the 10-17-year group. Three were so mild that they would not have been called influenza in the absence of the outbreak. Another boy in the 10-17-year group had been newly admitted and received the first dose of vaccine four days before developing influenza. Also, three girls in the 6-10-year age group became ill after the first dose of vaccine. Throat washings were collected on 11 of these 17 children, and 7 of these yielded Asian strain influenza on isolation.

Five cases of influenza occurred after the second dose of vaccine. Four of these five cases occurred the day after the second dose, and these were among children in the 6-10-year group. Two girls and two boys were ill. One girl and one boy were so mildly ill that their illnesses would not have been called influenza in the absence of the epidemic. Asian influenza virus was isolated from both of these.

The fifth case occurring after the second dose of vaccine was in a boy in the 10-17-year age group who became ill on Nov. 8, 1957. His case represents the last illness observed in the orphanage and the only case occurring after the second dose of vaccine was presumed to be effective. This case was very mild, with rise in temperature to 102.8 F (39.3 C), and lasted only 36 hours. Virus was not isolated from a specimen taken during his illness.

* 0 = No redness, no induration; 1 = pink, slight induration up to 15 by 15 mm.; 2 = red, indurated up to 25 by 30 mm.; 3 = red, induration greater than 25 by 30 mm.

† More than temporary induration, persisting as small nodule with brownish pigmentation.

The influenza morbidity for each age group revealed that 19 of 48 children (39.6%) in the 10-17-year group, 7 of 58 (12.1%) in the 6-10-year group, and none in the two younger age groups (1-3 and 3-6 years) became ill. It is important to note that the younger children were known to have been exposed to influenza even though no clinical influenza developed among them. One of the older girls in the 10-17-year age group, who became ill on Oct. 15, and another girl of this group, who became ill on Oct. 24, until they exhibited severe clinical manifestations of illness bathed and dressed the younger children each evening. Also, two other adults in charge of the preschool-aged children developed mild clinical influenza confirmed by serologic evidence of Asian strain virus. These persons were in constant association with the infants and younger children during their own illnesses, which occurred in late October after they had received their second dose of vaccine.

It is also noteworthy that the children in the 3-6-year age group had been under intensive observation during a special study of respiratory diseases for 10 months prior to and concurrent with the present study. None of these developed disease which could be considered to be even mild or atypical influenza, although some did show rhinitis with cough, fever, or malaise. These illnesses were no different from numerous such episodes experienced during the year. In fact, this group was remarkably free of all respiratory symptoms during the period of the present study. Although no definitive data are available regarding the incidence of clinical influenza among children under 6 years of age in the population of the city during the epidemic, it is our opinion, and that of pediatricians practicing in the community, that this age group was not spared from attack.

The duration of illness in the first cases observed was three to five days, usually three days, with the height of febrile response on the second day. It has already been noted that 5 of the 26 cases were of such a mild character that the diagnosis of influenza would probably not have been made in a nonepidemic year. In fact, no cases were considered severe, and no complications occurred. Immunization may have contributed to this.

There were only 6 systemic reactions to the antigen out of 320 immunization procedures. Four of these were after the first dose and two after the second. These consisted of malaise, anorexia, headache, and temperature rise to less than 100 F (37.8 C), with a duration of less than 24 hours. None of the children was known to be sensitive to eggs, and no immediate local protein reactions were seen, although some were observed in a group of medical students receiving the same antigen intradermally. Careful attention was given to the long-term effects of the local injection of the vaccine because of the persistence of the papule formed by the vaccine and the fact that this sometimes developed a brownish pigmentation which might cause concern from a cosmetic standpoint. The extent and character of these reactions are presented in table 2. These papules generally disappeared by six weeks, but the pigmentation persisted in some children at least up to three months and was usually about 3 to 5 mm. in diameter. In no case was it considered a contraindication for the use of the vaccine by the dermal route. It is evident from these data that the older children are apt to develop a more severe temporary reaction. Formation of pigmented papules has not been observed by one of us (L. C. W.) in persons receiving influenza vaccine intradermally from other sources.

The results of the HI tests performed on the youngest three age groups (1-3, 3-6, and 6-10) are presented in table 3. The 10-17-year age group is not included because of difficulties beyond our control in obtaining specimens. Since the illnesses had all occurred before the second dose of vaccine could be expected to be effective, the seven children in the 6-10-year age group with influenza are presented separately in the table from the others who did not become ill. The prevaccination titers were negative in all children in a 1:5 dilution, except for a single patient in the 6-10-year age group whose titer was 1:10. Postvaccination titers were not high but did show the effect of antigenic stimulation. A considerable number (92.7% of the total group) showed a twofold or greater rise in antibody titer, and 55.2% showed a fourfold or greater rise. The 6-10-year age group showed a greater response than either of the two younger age groups with regard to a fourfold or greater rise.

Comment

The pattern of the Asian influenza outbreak among these 168 orphanage children seems to have been influenced by the concurrent administration of the two doses of homologous virus vaccine given intradermally. The following points seem to suggest this.

First, both clinical and serologic evidence indicate that no Asian strain influenza had occurred in the children under 10 years of age up to the time they received the first dose of vaccine.

Second, a very large portion of all children showed at least a twofold rise in HI antibody titer by three weeks after the second dose. Among the children of the 6-10-year age group who did not develop clinical influenza, 78.7% showed at least a fourfold rise in HI antibody titer after receiving the second dose of vaccine. The fourfold or greater rises in HI antibody titer among the 1-3-year and 3-6-year age groups was 20.8 and 33.3% respectively. Since clinical influenza occurred in the 6-10-year age group, it is possible that inapparent infections may have contributed to the higher conversion rate or, possibly, the older children responded better in production of antibody. Conversely, children in the younger age groups either produced antibody poorly or did not have inapparent infections.

Third, the outbreak in the orphanage began in the older children Oct. 15-16, the exact time of the beginning of the epidemic in the city. A total of 19 cases (39.6%) occurred in children in the 10-17-year age group, and all but a single case occurred before the second dose of vaccine was given. The next younger age group experienced clinical influenza after it had subsided in the older age group. A total of seven (12.1%) in the 6-10-year age group were affected, and again the cases all occurred before the second dose of vaccine could become effective. No cases occurred in the two youngest age groups, 1-3 and 3-6 years of age, even though there was known contact with children with clinical cases who were harboring the virus.

Table 3.—*Increase in Hemagglutination Antibody Titer and Geometric Mean Titer to Asian Strain Influenza in Orphanage Children Three Weeks After Second Intradermal Dose of Homologous Vaccine*

		Rise in Titer				
		2-Fold or Greater		4-Fold or Greater

3-6	18	15	83.3	6	33.3	4.82
6-10						
Not ill	47	45	95.7	37	78.7	9.62
With influenza	7	7	100.0	5	71.4	12.60
Total	96	89	92.7	53	55.2	

* Reciprocals of mean titer. 0 equals <1:5, lowest dilution tested. Prevaccinal titers were all <1:5 with 1 exception.

Fourth, the epidemic in the city continued among school children, and the peak of the epidemic was reached about Nov. 4, 1957, and tapered off subsequently. All cases in the orphanage occurred between Oct. 15 and 31, except for a questionable single mild case on Nov. 8, 1957. It would appear, then, that the orphanage outbreak had substantially ceased before the citywide epidemic had reached its peak.

Interest in the intradermal route for vaccination of children against influenza was heightened during the recent Asian influenza epidemic primarily because of shortage of vaccine and the fact that children tend to exhibit reactions to large doses of vaccine given subcutaneously. The efficacy of the intradermal route for immunization against other diseases has been pointed out in the past, and it was considered important to reevaluate this method of injection in influenza.[3] Some studies have shown that the antibody response to 0.1 or 0.2 ml. of vaccine given intradermally as a single dose or in two doses of the same amount given approximately one week apart compares very favorably with 0.5 to 1.0 ml. given subcutaneously.[4] Others[5] indicate that this may not be the case. The recent studies of McCarroll and Kilbourne[6] suggest that the division of the vaccine into two doses given one week apart subcutaneously will induce an antibody response superior to that of a single injection by the same route containing the same total dose. They also compared 0.1-ml. and 0.2-ml. doses by both intradermal and subcutaneous routes and found the latter route at least equal in antigenic efficiency. This would seem to indicate that the timing of the injections may be more important than the route of inoculation of small dosages. This important observation deserves further study. Davenport,[7] noting the failure to produce over 10 million doses of vaccine for civilian use prior to the epidemic peak of Asian influenza in 1957, suggests that reliance can not be placed on strain-specific vaccine and a second approach, namely, a panvalent vaccine, may achieve our objectives to control influenza.

Glazier[8] has recently reported immunization against influenza in children to be effective in the face of an epidemic. Of particular interest in relation to the present study are his group-3 cases. None of 241 children in this group who received 0.03 ml. of influenza A and B vaccine intradermally, followed within seven days by 0.5 ml. given subcutaneously, just prior to or at the beginning of the epidemic developed influenza. Of 61 children in the same group who received only the initial dose, 7 developed influenza. In his control group of 122 unimmunized children, 21 had moderate or severe influenza during the epidemic.

Our observations on the course of the influenza outbreak in an orphanage, presented here, appear to indicate that the intradermal route was effective in preventing the spread of the disease to younger age groups, although other factors may possibly have played a role. Our experience justifies continued use of the intradermal route in children and further studies of its effectiveness in older age groups.

Summary

Homologous Asian strain influenza vaccine was given intradermally in two 0.1-ml. doses one week apart to 168 orphanage children from 1 to 17 years of age during the early phase of an outbreak of Asian influenza. All clinical cases of influenza occurred before the second dose of vaccine could become effective, except for a questionable mild case which occurred later. The cases were confined to the older children, with 40% of those in the 10-17-year age group and 12% of those in the 6-10-year age group becoming ill. No cases occurred among the children under 6 years of age. Hemagglutination-inhibition titers were studied on prevaccinal and postvaccinal serum samples, and reactions to the vaccine were noted. The data appear to substantiate the effectiveness of intradermal vaccination against influenza in children in an epidemic situation.

EXPERIENCES WITH GENERAL ANESTHESIA IN PATIENTS WITH FAMILIAL DYSAUTONOMIA

Marilyn M. Kritchman, M.D., Herman Schwartz, M.D.
and
Emanuel M. Papper, M.D., New York

The syndrome familial dysautonomia includes a combination of congenital abnormalities and clinical manifestations that make a patient a poor candidate for general anesthesia. Striking features are indifference to pain and diminished lacrimation, which predispose to corneal ulceration, and poor vasomotor control, which predisposes to hypertension during emotional crises and to hypotension during anesthesia. Three cases are described in detail. Among eight patients in whom this syndrome was observed, severe hypotension during anesthesia occurred six times and cardiac arrest twice. When this condition is suspected, a complete preoperative evaluation is needed. Patients who have this condition do not tolerate thiopental sodium or tribromoethanol as anesthetic agents. If local anesthesia after premedication with chlorpromazine is not suitable, the alternative is premedication with chlorpromazine and belladonna drug followed by a volatile general anesthetic.

Since 1949, when familial dysautonomia was described by Riley and co-workers,[1] eight patients with this disease have been anesthetized for 27 surgical procedures at the Columbia-Presbyterian Medical Center. The morbidity from the anesthesia in these patients was high. The difficulties in providing anesthesia safely were serious. Since the disease is rare and the opportunities to administer anesthesia unusual, a review of the problems presented and the details of anesthetic management appeared desirable.

Diagnosis

Familial dysautonomia is a congenital condition frequently seen in siblings and characterized by specific disturbances of the nervous system. The most striking clinical manifestations are associated with aberrations in autonomic nervous system function. All responses to sensory stimuli appear to be either particularly exaggerated or absent. Almost all of the reported patients are small in stature and undernourished. The age at which they have been seen has rarely exceeded 20 years, the majority ranging from 1 to 12 years of age. Many deaths have occurred in the first two to three years of life, but many such patients appear capable of indefinite survival. The oldest currently is 27 years of age.

Table 1 outlines the salient features of the disease.[2] Certain characteristics are more pertinent to the anesthetic management and bear emphasis. Among the disorders of the autonomic nervous system, peripheral vascular dysfunction is prominent. These patients exhibit skin blotching with excitement or ingestion of food. Hypertension in response to emotional stimuli is usually, though not always, present.

Normal individuals show a slight rise in both systolic and diastolic pressures when changing from the supine to the erect posture. In contrast, these patients show a fall in systolic and an even more striking fall in diastolic pressure during the same change in posture. All of the reported patients have exhibited postural hypotension.[3]

Especially in the early years, bronchopneumonia and atelectasis are apt to occur. Moloshok and Moseley [4] believe this is a consequence of excessive mucoid secretions. According to Riley,[2] however, a poor swallowing reflex with aspiration of food or secretions probably is an important contributing factor. As the children grow older, pulmonary complications tend to diminish.

Poor temperature control is another feature of the disease, and even mild infections are accompanied by high fevers. At times, bouts of elevated temperature occur with no overt evidence of infection. Fever and the vomiting which is characteristic of the syndrome often complicate the postoperative period.

The sensory disturbance of importance is indifference to pain. This is not true anesthesia, since the patients can readily identify pin prick. It represents a lack of awareness of discomfort. The diminished lacrimation and corneal anesthesia which are present contribute to the frequency of corneal ulceration. Healing of corneal ulceration is slow and often requires surgical creation of intermarginal lid adhesions.[5] Other characteristics of the disease include poor muscle coordination with absent or hypoactive deep tendon reflexes, dysarthria,

---

emotional lability, and drooling beyond the usual age. Death usually occurs after infection or aspiration of vomitus.

There is no satisfactory treatment at the present time. Prefrontal lobotomy, electroshock, tentorial splitting, and lumbar sympathectomy have all failed. Chlorpromazine has proved useful for the treatment of prolonged vomiting. If given at the onset of an attack in combination with phenobarbital, the vomiting is often stopped and the period of disability seems shortened.

Thirteen postmortem examinations have been reported without evidence of consistent or characteristic abnormalities of the central nervous system. Three showed brain lesions, one had a thalamic cyst destroying the dorsal medial nucleus, one had marked degenerative changes in the reticular substance of the pons and medulla, and one had multiple brain abscesses.[6] Psychiatric studies reveal a behavior pattern most closely resembling that of children who suffer from diffuse organic disorders of the brain.[7] To account for the widespread central and peripheral involvement, Riley [2] and others have postulated a fundamental enzyme disturbance in the nervous system as the causative factor.

Analysis of Cases

Eight patients ranging in age from 9 months to 12 years received general anesthesia 27 times for a variety of surgical procedures (table 2). Preanesthetic medication with a belladonna derivative alone was administered in 11 cases, an opiate combined with belladonna in 4, barbiturate and opiate with belladonna in 5, barbiturate with belladonna in 2, chlorpromazine combined with an opiate and belladonna in 1, and chlorpromazine combined with a barbiturate and belladonna in 1. In the remaining three cases no premedication was used.

Different anesthetic agents were tried. Tribromoethanol (Avertin) alone was used three times, and tribromoethanol followed by diethyl ether was used five times. Vinyl ether followed by diethyl ether was administered twice, cyclopropane followed by diethyl ether in two cases, and ethyl chloride followed by diethyl ether twice. Diethyl ether was given alone in six cases, thiopental sodium followed by nitrous oxide-oxygen in four, tribromoethanol followed by thiopental sodium and nitrous oxide-oxygen in one, thiopental sodium alone in one, and open insufflation of cyclopropane in one.

Complications during anesthesia were frequent and related specifically to the cardiovascular system. Severe hypotension occurred six times, once requiring cancellation of the operative procedure. Hypotension resulted in two instances of cardiac arrest, with successful resuscitation by cardiac massage and efficient ventilation with oxygen.

The most prominent postoperative complication was pulmonary. Bronchopneumonia was present five times in this series, accompanied twice by atelectasis. Two patients exhibited cyanosis during the recovery from anesthesia. There were three patients who developed the cyclic vomiting and spiking temperatures characteristic of this disease. The following three case reports are described in detail to illustrate the cardiovascular collapse which may occur.

Report of Cases

Case 1.—An 18-month-old girl, weighing 12 lb. (5.4 kg.), had the characteristic clinical signs of familial dysautonomia. She was undernourished and dwarfed and had frequent bouts of vomiting and bronchopneumonia and a labile hypertension. An arthrogram was scheduled to establish the diagnosis of congenital hip dysplasia. On two previous occasions the procedure was canceled because of persistent bronchopneumonia. On this occasion a preoperative chest film showed normal findings. Scopolamine, 0.2 mg., was given one hour before operation. The patient arrived in the operating room with a dry mouth and was crying. After a cut-down incision for intravenous cannulation was performed with use of local anesthesia, 2 cc. of a 1.25% solution of thiopental sodium was injected intravenously. A mask was applied, and a mixture of 60% nitrous oxide and 40% oxygen was administered through a nonrebreathing system. A metal oral airway was inserted after 12.5 mg. more of thiopental sodium had been given. The patient coughed twice and became apneic, although the airway was clear and the chest easily inflated. The pulse slowed to 10 beats per minute, and the blood pressure could not be measured. Positive pressure oxygen was given by mask, and ephedrine (5 mg.) was in-

TABLE 2.–*Results of General Anesthesia in Eight Patients with Familial Dysautonomia*

Case No.	Age at Operation, Yr.	Symptoms	Operation	Premedication	Anesthetic Agent	Complications	
						Anesthetic	Postoperative
1	2	Hypertension, pulmonary symptoms	Arthrogram	Scopolamine, 0.2 mg.	Thiopental sodium, nitrous oxide-oxygen	Hypotension	Cyclic vomiting, aspiration pneumonia
2	7	Hypertension	Myelogram	Morphine sulphate, 3 mg.	Tribromoethanol (Avertin), 100 mg./kg. of body weight	None	None
			Correction of varus deformity of right foot	Meperidine (Demerol), 10 mg., scopolamine, 0.2 mg.	Cyclopropane, nitrous oxide-oxygen, ether	None	Cyanosis in recovery room
3	1⅙	Pulmonary symptoms	Suture of tongue	Chlorpromazine (Thorazine), 10 mg., secobarbital (Seconal), 15 mg., scopolamine, 0.2 mg.	Vinyl ether (Vinethene) nitrous oxide-oxygen	Labile pulse	None
4	6	Hypertension, pulmonary symptoms	Stellate block	None	Cyclopropane	None	None
			Creation of lid adhesions	Secobarbital, 60 mg., scopolamine, 0.25 mg.	Vinyl ether	None	None
	7		Lysis of adhesions	Secobarbital, 60 mg., scopolamine, 0.2 mg., morphine sulphate, 3 mg.	Tribromoethanol, 50 mg./kg. of body weight, ether	None	None
5	1½	(Normotension, no pulmonary symptoms)	Creation of lid adhesions	Atropine, 0.1 mg.	Ethyl chloride, ether	None	None
	5½		Lysis of adhesions	Meperidine, 20 mg., scopolamine, 0.2 mg.	Tribromoethanol, ether	None	None
6	9	Hypertension, pulmonary symptoms	Topectomy	Morphine sulphate, 7 mg., scopolamine, 0.3 mg.	Tribromoethanol, 70 mg./kg. of body weight, thiopental sodium, nitrous oxide-oxygen, meperidine	Hypotension, cardiac arrest	Bronchopneumonia with atelectasis, cyclic vomiting
	10		Lobotomy	Amobarbital (Amytal), 100 mg., meperidine, 50 mg., scopolamine, 0.3 mg.	Thiopental sodium, vinyl ethyl-ether, nitrous oxide-oxygen	Hypotension	Bronchopneumonia with atelectasis
7	6	(Normotension, no pulmonary symptoms)	Creation of lid adhesions	Meperidine, 25 mg., chlorpromazine, 10 mg., scopolamine, 0.2 mg.	Cyclopropane, nitrous oxide-oxygen, ether	None	None
8	¾	Hypertension, pulmonary symptoms	Creation of conjunctival flap	Atropine, 0.1 mg.	Ether	None	Bronchopneumonia
	1		Release of conjunctival flap	Atropine, 0.1 mg.	Ether	None	None
	2		Creation of lid adhesions	Atropine, 0.1 mg.	Ether	None	None
	2½		Release of adhesions	Atropine, 0.1 mg.	Ether	None	None
	3		Creation of adhesions	Atropine, 0.1 mg.	Ether	None	None
	3		Creation of lid adhesions	Atropine, 0.1 mg.	Tribromoethanol, 100 mg./kg. of body weight, ether	None	None
	4		Inversion of eyelashes	Atropine, 0.2 mg.	Tribromoethanol, 100 mg./kg. of body weight	None	None
	4½		Bronchoscopy, bronchography	None	Ethyl chloride, ether	None	Hypotension, cyanosis
	4½		Tonsillectomy, adenoidectomy	Secobarbital, 30 mg., scopolamine, 0.2 mg.	Ether	None	None
			Division of tentorium	Scopolamine, 0.1 mg.	Ether, thiopental sodium, nitrous oxide-oxygen	Hypotension throughout	Febrile for 10 days
	5		Creation of adhesions	None	Thiopental sodium	None	None
	5		Creation of lid adhesions	Atropine, 0.1 mg.	Tribromoethanol, 95 mg./kg. of body weight, ether	None	None
			Creation of lid adhesions	Secobarbital, 45 mg., codeine, 45 mg., scopolamine, 0.3 mg.	Tribromoethanol, 95 mg./kg. of body weight	None	None
	10		Superficial keratectomy	Secobarbital, 50 mg., morphine sulphate, 5 mg., scopolamine, 0.4 mg.	Tribromoethanol, 50 mg./kg. of body weight, nitrous oxide-oxygen, ether	Hypotension	None
	12		Superficial keratectomy	Secobarbital, 100 mg., morphine sulphate, 8 mg., scopolamine, 0.3 mg.	Thiopental sodium, succinylcholine, nitrous oxide-oxygen	Cardiac arrest	Pleural effusion, *pneumonia*, cyclic vomiting

jected intravenously. Within a few moments the blood pressure returned to hypertensive levels, the pulse rate accelerated to 160 per minute, and spontaneous respirations resumed. The procedure was abandoned, and the patient returned to bed fully responding. On the first postoperative day, she aspirated a feeding and developed a complete atelectasis of the right lung. Endotracheal intubation followed by adequate tracheobronchial aspiration produced complete reexpansion of the lung, and she made an uneventful recovery. One month later this patient developed a corneal ulceration. Intermarginal lid adhesions were produced during local anesthesia. Chlorpromazine (5 mg.) was used for premedication.

CASE 6.—A 9-year-old girl, weighing 50 lb. (22.7 kg.), had hypertension, pulmonary symptoms, and cyclic vomiting. In addition she exhibited severe emotional instability. A topectomy was contemplated. Premedication consisted of morphine sulphate, 7 mg., and scopolamine, 0.3 mg., given one and one-half hours before operation. She arrived in the operating room awake and apprehensive. Tribromoethanol, 1.6 Gm. (70 mg. per kilogram of body weight), was given rectally and partially expelled. After a spray of a 2% solution of tetracaine hydrochloride to the larynx and trachea, endotracheal intubation was performed. The endotracheal tube was connected to a Heidbrink circle filter and a mixture of 60% nitrous oxide and 40% oxygen was administered. Supplementary intravenous injections of a 3% solution of thiopental sodium in increments of 60 mg. and meperidine in 5-mg. doses were given. Hypotension developed during the induction and persisted, with a systolic pressure of 80 mm. Hg, in spite of administration of ephedrine (25 mg. intravenously and 25 mg. intramuscularly) and methamphetamine (Methedrine) (5 mg. intravenously). The blood pressure remained at 80/60 mm. Hg for three hours and then fell to 60/40 mm. Hg. By this time, 900 mg. of thiopental sodium and 40 mg. of meperidine had been given. Methamphetamine (5 mg. intravenously) had no effect, and cardiac arrest occurred. The chest was opened, and cardiac massage produced a prompt return of spontaneous beating. The postoperative course was complicated by a right lower lobe atelectasis which responded to antibiotic therapy.

The patient developed a more tractable personality, but this improvement was temporary. Four months later she was scheduled for bilateral prefrontal lobotomy. Premedication consisted of amobarbital (Amytal) sodium, 100 mg. given one and one-half hours preoperatively, and meperidine, 50 mg., and scopolamine, 0.3 mg., given one hour before operation. She was well sedated without appearing depressed. Sixty milligrams of a 3% solution of thiopental sodium was given. Her respiratory rate slowed to 8 per minute and her pulse to 60. Administration of 100% oxygen with positive pressure brought an immediate return of the pulse rate to 120 and respirations to 20 per minute. An open-drop vinyl ether–diethyl ether sequence followed uneventfully. The patient was intubated, and a mixture of 60% nitrous oxide and 40% oxygen was administered through a nonrebreathing system. Thiopental sodium, 30-to-60-mg. increments of a 3% solution, was added, sufficient to prevent movement of the patient. In three hours a total of 450 mg. was given. The blood pressure ranged from 100/60 to 80/50 mm. Hg, the pulse from 80 to 100 per minute, and the respiratory rate from 15 to 20 per minute. The postoperative course was complicated again by a right lower lobe bronchopneumonia and cyclic vomiting.

CASE 8.—A 12-year-old boy, weighing 101 lb. (45.8 kg.), had had 13 surgical procedures with general anesthesia from the age of 9 months until he was 10 years of age. On two previous occasions he developed severe hypotension, once after thiopental sodium administration and once after tribromoethanol and diethyl ether administration. He was scheduled for a superficial keratectomy. Premedication consisted of secobarbital (Seconal), 100 mg. given one and one-half hours preoperatively, and morphine sulphate, 8 mg., and scopolamine, 0.3 mg., given one hour before operation. He arrived in the induction room in an apprehensive state. Thiopental sodium, 150 mg. of a 3% solution and succinylcholine, 40 mg., were given intravenously. Endotracheal intubation was performed after 60 mg. of a 4% solution of cocaine was sprayed into the pharynx and trachea. Anesthesia was maintained with a mixture of 70% nitrous oxide and 30% oxygen administered through a Heidbrink circle filter with an overflow of gas escaping from the system with each breath. Thiopental sodium, 30-to-60-mg. increments of a 3% solution, was used to supplement the nitrous oxide analgesia. A total of 300 mg. had been administered when cardiac arrest occurred suddenly during the operation. There was no detectable preexisting hypotension. The chest was opened and the heart massaged within 60 seconds. Resuscitation was successful, and the patient reacted promptly on discontinuance of the anesthesia. Postoperative cyclic vomiting and a left pleural effusion and pneumonitis were present for one week, followed by complete recovery.

Comment

Patients with familial dysautonomia are grave anesthetic risks. The labile cardiovascular system, frequent bronchopneumonia, hypersalivation with aspiration, hyperemesis, and emotional instability are severe problems for the anesthesiologist.

Preoperative examination must be as complete as possible. In addition to a blood cell count and urinalysis, a chest film is necessary. If cyclic vomiting is present, electrolyte and fluid imbalance must be corrected. Preanesthetic medication with chlorpromazine, 0.5 mg. per pound, is proving valuable both as an emotional stabilizer and as prophylaxis against postoperative vomiting. Enough barbiturate (0.5 mg. per pound) and narcotic (0.05 mg. per pound of morphine or 0.5 mg. per pound of meperidine) should be added to insure a well-sedated patient on arrival in the operating room. The use of a belladonna drug has been questioned by some because of the tendency to thicken bronchial secretions and possibly contribute to atelectasis. However, adequate doses of atropine or scopolamine diminish salivation and provide for smoother induction and maintenance of anesthesia.

The presence of a labile cardiovascular system demands a flawless anesthetic technique with adequate ventilation. Postural hypotension adds to the circulatory problem. Once the patient is anesthetized, positional changes should be avoided if possible. If movement of the patient proves to be necessary, it should be performed very slowly. The blood pressure must be measured frequently to ascertain early hypotensive changes. Hypotension is serious and may be the prelude to cardiocirculatory collapse. Early detection and treatment is essential to prevent complete circulatory failure. Vasopressors, e.g., ephedrine (5 to 25 mg.) and methedrine (2 to 5 mg.), often provide prompt restitution of the blood pressure. Where they fail, a dilute drip of levarterenol (1 to 2 mg. in 500 ml. of a 5% solution of glucose in water) may be tried.

Severe arterial hypotension or cardiac arrest occurred six times in this series. In five of these cases thiopental sodium was given intravenously, and once tribromoethanol per rectum was used. Although ether, vinyl either, or cyclopropane-ether were most frequently used, hypotension was not encountered with these agents. The precise reasons for the difficulties with thiopental sodium and tribromoethanol are unknown.

With only eight cases analyzed retrospectively, no predictably safe method of anesthetic management has been found. The difficulties encountered with the agents previously used suggest that the volatile agents which can be eliminated rapidly are superior to those which are metabolised. Thiopental sodium and tribromoethanol created difficult problems in management and are avoided now. Since an elevated pain threshold is often present, it is possible to perform minor surgical procedures with use of local anesthesia. Four patients, not included in this series, had minor surgery satisfactorily performed with local anesthesia after premedication with chlorpromazine, a barbiturate, and meperidine. In view of the high morbidity with general anesthesia reported here, local anesthesia reinforced with chlorpromazine and sedatives is suggested wherever practical.

Summary

Eight patients with familial dysautonomia received general anesthesia for 27 surgical procedures. Serious morbidity was high. Severe hypotension occurred six times, leading to cardiac arrest twice. Bronchopneumonia was a frequent postoperative complication. All of the cardiovascular problems were associated with the use of thiopental sodium or tribromoethanol (Avertin). As guides to safer management, the following points are suggested: (1) a complete preoperative evaluation, including chest x-ray, (2) premedication with chlorpromazine and a belladonna drug, and (3) use of the volatile anesthetic agents, if local anesthesia after premedication with chlorpromazine is not suitable.

TRANQUILLIZERS IN PSYCHIATRY.—There are two groups of drugs, the *phenothiazine compounds and the Rauwolfia alkaloids, which have a specific action* on some of the symptoms of psychosis. Alone or in combination with other drugs they are effective in acute and chronic psychoses mainly characterized by psychomotor overactivity and excitement. States of depression or stupor either do not respond, or are better treated by other means, such as convulsive therapy or analeptics. The neuroses are no more responsive than to other agents. The phenothiazine compounds are in general more effective than the Rauwolfia alkaloids, although individual patients show marked differences in their responses to one or other of the groups of drugs, and combinations of a phenothiazine compound with reserpine or with another phenothiazine compound, e. g. chlorpromazine and pecazine, may be more effective than either singly. Little can be said at present about specific indications for particular drugs. Their action, like the action of other forms of therapy in psychiatry, cuts across diagnostic categories. The most effective dose of both groups is reached at a level where they cause motor slowing and rigidity: a level when Parkinsonian symptoms are appearing. Parkinsonian symptoms can be controlled in some cases with anti-Parkinsonian drugs if it is necessary to maintain a high dosage level. Usually the dose can be reduced once symptoms are under control, and patients may be discharged from hospital and maintained on quite low doses. When patients are discharged from hospital after treatment with tranquillizers, the burden of their supervision usually falls on the general practitioner, although some hospitals are now starting special maintenance clinics for this purpose. It is clearly important that the practitioner should not only recognize the possibility of toxic symptoms, but should also be aware of the importance of maintenance therapy, which for some patients is as important for the control of psychiatric illness as it is in the case of digitalis for the cardiac patient.—D. M. Leiberman, M.D., and G. F. Vaughan, M.B., Tranquillizers, *The Practitioner,* October, 1958.

THE EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES

Dean F. Smiley, M.D., Evanston, Ill.

A system of qualification examinations has been developed in order to insure uniformity and fairness in the testing of foreign-trained physicians for admission to internship or residency training in the hospitals of the United States. The Educational Council for Foreign Medical Graduates (ECFMG) gave its first examinations in 1958. These have been modified in the light of accumulating facts, especially as regards language difficulties. The fourth examination, Sept. 22, 1959, will be given not only in the United States but also in over 50 foreign centers. The candidate who passes can safely assume that his knowledge of medicine and command of English are adequate for him to profit by his experience in this country, and an American hospital accepting him can feel assured that he is qualified to render effective service as intern or assistant resident.

The Educational Council for Foreign Medical Graduates (ECFMG) opened its doors Oct. 1, 1957. On March 25, 1958, it held its first American Medical qualification examination; on Sept. 23, 1958, its second examination; and on Feb. 17, 1959, its third examination.

Qualification Examinations

The first qualification examination was given March 25, 1958, to 298 foreign medical graduates who were already in the United States. It was offered in only 17 U. S. medical schools. Of the 298 taking the examination, 152 (51%) attained a score of 75% or better and were granted standard ECFMG certificates. Only one candidate failed to pass the ECFMG English test.

One fact that came out of this first examination was that many of these foreign medical graduates, even after experience in an American hospital, were slow readers of English. Twenty-eight of them failed to finish the morning portion of the examination and left a block of unanswered questions at the end of that session. As the result of this experience, the total number of questions was reduced from 400 to 360 and an additional time allowance of 30 minutes was added.

The second examination, on Sept. 23, 1958, was given to 844 candidates in about 30 U. S. medical schools and in about 30 examination centers set up in foreign countries with well-instructed American-national proctors in charge.

Of the 844 foreign medical graduates who took this examination, 418 (49.5%) attained a score of 75% or better and were granted standard ECFMG certificates. Of the 844, there were 7 who failed to pass the ECFMG English test and 9 who received a mark of "questionable pass" in it.

This was not too bad a showing for the group as a whole, but further breakdown of the figures showed that for those who took the examination in their home country without ever having had experience in an American hospital, many of them without experience in an English-speaking country, the results were not nearly as favorable. Of the 707 foreign medical graduates taking this examination in the United States, a total of 371 (52.4%) attained scores of 75% or better and 193 (27.3%) attained scores of 70 to 74%. In contrast, of the 137 foreign medical graduates taking the examination overseas only 47 (34.3%) attained scores of 75% or better and only 33 (24.1%) attained scores of 70 to 74%.

Failure to understand English was apparently much more of a stumbling block for the overseas candidate than for the stateside candidate. Of the 137 overseas candidates, 7 failed the ECFMG English test and 3 were listed as "questionable pass." In contrast, of the 707 stateside candidates, none failed the English test and only 6 were listed as "questionable pass."

With all these facts in mind, the ECFMG's Examinations Committee concluded that it would be quite unfair and unwise to exclude from participation in U. S. hospital internship and residency training 65.7% of the foreign-trained physicians applying in their home country, when experience has shown that the majority overcome the language barrier rapidly when once established in a U. S. hospital.

On the recommendation of the Examinations Committee, the Board of Trustees of the ECFMG voted to issue a temporary certificate to those candidates passing the English test and attaining a score of 70 to 74% in the qualification examination. This certificate would be good for admission to

---

Executive Director, Educational Council for Foreign Medical Graduates.

internship or assistant residency training for a period not to exceed two years. If, within the two years, the candidate does not retake and pass the examination with a score of 75% or better, he would be expected to return to his home country.

Of the 844 candidates taking the second examination, 418 (49.5%) therefore received ECFMG standard certificates and 226 (26.8%) received ECFMG temporary certificates. Eighty (58.4%) of the 137 candidates taking the examination overseas obtained certificates declaring them qualified to undertake hospital training in the United States. Of the overseas candidates, 34.3% won standard certificates and 24.1% won temporary certificates.

The third examination was given Feb. 17, 1959, to 1,772 foreign medical graduates in 33 examining centers in the U. S. and 44 centers overseas.

Of the 1,278 candidates taking the examination in U. S. centers, 616 (48.2%) obtained scores of 75% or better and received ECFMG standard certificates and 341 (26.7%) obtained scores of 70 to 74% and received ECFMG temporary certificates. None of these candidates failed the ECFMG English test, but three were listed as "questionable pass."

Of the 494 candidates taking the examination in the 44 overseas examination centers, 153 (31%) obtained scores of 75% or better and received ECFMG standard certificates and 110 (22.3%) obtained scores of 70 to 74% and received ECFMG temporary certificates. There were in this group 22 failures and 23 listed as "questionable pass" in the ECFMG English test. There was one foreign center in which 3 out of 5 candidates had serious difficulty with the English test and two foreign centers in which approximately 5 out of 10 candidates had serious difficulty with the English test.

Future Examinations

The fourth American medical qualification examination is scheduled for Sept. 22, 1959. Applications and credentials must be in the hands of the ECFMG, 1710 Orrington Ave., Evanston, Ill., no later than June 22, 1959. Examination centers will be activated in the cities listed in the table.

The examinations for 1960 are scheduled as follows: March 16, 1960 (with deadline for application Dec. 16, 1959), and Sept. 21, 1960 (with deadline for application June 21, 1960).

Conclusions

The Educational Council for Foreign Medical Graduates is growing rapidly. The number of candidates given the American medical qualification examination has risen rapidly from 298 on March 25, 1958, and 844 on Sept. 23, 1958, to 1,772 on Feb. 17, 1959. Over 1,000 candidates are already signed up for the examination on Sept. 22, 1959.

Largely because of the language difficulties, the issuance of temporary two-year certificates to those attaining scores of 70 to 74% in the examination has been found necessary. The qualifying examination is now being offered in 34 United States cities and in 52 foreign cities twice each year. Additional centers are in the process of being organized.

American hospitals accepting as interns or assistant residents the foreign medical graduates who hold either standard or temporary certificates should feel safe in assuming that these candidates are bona fide physicians who have had a minimum of 18 years of formal training, at least 4 of the years in a recognized medical school, and that their knowledge of medicine and their command of English are ample to enable them to serve effectively as interns or assistant residents.

LIPID STUDIES IN HEALTH AND DISEASE

PRELIMINARY REPORT OF THE RESULTS OF LIPID DETERMINATIONS IN A GROUP OF NORMAL MALE OFFICERS AND PATIENTS WITH VASCULAR DISEASES

Brig. Gen. Thomas W. Mattingly, Lieut. Col. Loren F. Parmley Jr., (MC), U. S. Army
Emmett L. Durrum, M.D., Elizabeth R. B. Smith, Ph.D.
and
Marion R. Hyatt, B.S., Washington, D. C.

In an effort to determine the diagnostic and prognostic value of certain laboratory data in atherosclerosis, values obtained from 294 normal healthy male officers were compared with values obtained from 205 patients with myocardial infarction, 101 with angina, 77 with arteriosclerosis obliterans, 99 with hypertensive cardiovascular disease, and 100 under observation for cardiovascular disease. The data concerned total serum cholesterol levels and two lipoprotein fractions. Significant differences between groups were found, but variations from person to person within groups were too great to permit identification and prediction of atherosclerosis in individuals. The serum lipid values of 10 normal persons who subsequently showed severe cardiovascular symptoms (fatal in four cases) were not consistently high. The serum cholesterol level was as informative as data from the more elaborate procedures. When it is high in a patient, the physician should look for other evidence of premature vascular disease.

Recognition of the increasing importance of atherosclerosis as a major cause of death and disability has stimulated extensive investigation in this field during the past decade. Atherosclerosis is no longer regarded as the inevitable result of age or "wearing out" of the arteries but is now considered a disease entity. Autopsy studies suggest that almost all North American adult males have some coronary artery atherosclerosis and that this process can begin early in adult life and may often exist in an occult form for years before recognizable clinical manifestations appear.[1]

Cholesterol is the chief chemical constituent in the atheromatous plaque, the pathological hallmark of atherosclerosis. The pathogenesis or mechanism of atherogenesis is not known, and the question has been a subject of widespread speculation and international research. Among the many causes and predisposing factors considered have been heredity; type of vascular construction; injury to the vascular wall by infection, trauma, stress, and increased vascular tone and intravascular pressure; faulty enzymatic activity in lipid metabolism; or a basic abnormality in lipid metabolism based on faulty diet.

The frequent finding of a high concentration of serum cholesterol in persons with atherosclerosis and the production of experimental atherosclerosis in laboratory animals by feeding them high cholesterol-lipid diets have suggested that there is an etiological relationship between a defect in lipid metabolism and human atherosclerosis. Epidemiologic studies of sample populations have statistically suggested that an association exists between high-fat diets and higher serum cholesterol levels and a high incidence of atherosclerosis. These combined observations have provided an indirect method of study which only furnishes information about groups of persons and may or may not apply to a particular person whom we may wish to evaluate in terms of absence or presence of atherosclerosis or susceptibility to this condition.

One important phase now under investigation, evaluation, and debate is the relationship of cholesterol and other lipids to atherosclerosis and the part they play as possible etiological or predisposing factors, indicators of existing disease, or predictors in persons who may be susceptible to this disease. The potentialities of a method or a blood measurement for the early identification of persons with atherosclerosis or a predisposition to this disease attracted the attention of military physicians whose primary responsibility is selecting the physically fit and maintaining the health of military personnel.

The present study was initiated at Walter Reed Army Hospital early in 1951 with the assistance of the department of pharmacology of the Walter Reed Army Institute of Research. Its aim was to evaluate the reliability of the various methods of lipid determinations in identifying and predicting atherosclerosis, especially coronary atherosclerosis. Measurements giving promise of value at that time were (1) serum cholesterol concentration,[2] (2) serum

normal subjects, but the increases were not as great as among those with definite clinical coronary disease. The individual variations in each group were great and the differences between the values of the normal and the diseased persons were small, thus preventing efficient application of the clinical theory of identification and prediction of atherosclerosis.

In this study, the elevation of the serum cholesterol level was greater and more distinctive in the group with proved atherosclerosis than were the S_f 12-20 and S_f 20-100 values for lipoproteins. Preliminary follow-up findings in the normal group indicate a better predictive value of cholesterol determinations as indicated by the subsequent development or recognition of atherosclerotic processes in those previously regarded as normal. Periodic repeated evaluation and long-term clinical follow-up studies of this normal group and similar groups by other investigators are necessary before the true predictive value of lipid determinations in atherosclerosis is established.

The serum cholesterol level measurement provides as much information as other more elaborate and expensive chemical and physical procedures for the measurement of lipoprotein levels, and serious consideration should be given to its addition to periodic health examinations to aid in identifying disturbances in lipid metabolism which may indicate a predisposition to or the presence of atherosclerosis. The presence of an elevated cholesterol value in an otherwise normal young adult male should encourage a search to uncover further evidence of premature vascular disease.

APPENDICITIS AND DIABETES.—When acidosis begins to be severe the diabetic patient develops pain and tenderness in the abdomen which closely simulates peritonitis secondary to appendicitis. To operate upon a patient for appendicitis, only to find that one is dealing with diabetic acidosis, is a very unfortunate error and may be disastrous. An awareness of the symptoms and findings of diabetic acidosis together with a few simple laboratory tests will usually make a proper diagnosis possible. One should bear in mind, however, that a diabetic patient in acidosis can develop appendicitis, and making the differential diagnosis in this case may be a real challenge to the surgeon. In both disease processes abdominal pain, nausea, vomiting, abdominal tenderness, elevated temperature and leukocytosis may occur. Usually the symptom of pain occurs first in appendicitis and the symptom of vomiting occurs first in diabetic acidosis. Another helpful differential point is that in appendicitis the physical signs may be more localized, and in diabetic acidosis they may be more generalized throughout the abdomen. Localized rigidity is unlikely in diabetic acidosis.—D. H. Wagner, M.D., The Preparation and Care of Diabetic Patients Requiring Surgery, *Surgical Clinics of North America*, February, 1959.

SPECIAL ARTICLES

The following two papers report studies done at the request of the Committee on Amphetamine Drugs and Athletes of the Board of Trustees of the American Medical Association. These studies represent a part of the Committee's efforts to help determine the effects of such drugs on athletic performance and the extent, if any, of their use in sports. Other findings and the recommendations of the Committee have been submitted to the Board of Trustees and will subsequently be reported to the profession and to the public.

AMPHETAMINE SULFATE AND ATHLETIC PERFORMANCE

I. OBJECTIVE EFFECTS

Gene M. Smith, Ph.D.
and
Henry K. Beecher, M.D., Boston

The study presented here was designed to answer the question of whether or not amphetamine sulfate ("pep pills") improves athletic performance in trained athletes.

Preliminary Considerations

Controlling Factors in Planning.—We knew at the outset that many variables might influence the effect of amphetamine on athletic performance: dose level; time after medication at which event was performed; whether the subject was rested, slightly fatigued, or severely fatigued; type of athletic event performed (brief intense effort versus prolonged, less intense effort, or event where performance is largely dependent on form versus event where performance is largely dependent on strength); whether the subject performed the event competing with the clock or competing with another athlete; whether the athlete knew he was receiving a drug (and his expectations concerning its effect); whether or not the subject was in top form; mood; and motivation.

An initial exploratory phase of the investigation yielded data which did not demonstrate conclusively that amphetamine either did or did not help athletic performance, on the average. However, both the measured performance data and the subjective data obtained by interviewing the athletes indicated that at least some athletes could obtain consistent and repeatable improvements in performance by taking amphetamine sulfate in the dose of 14 mg. per 70 kg. of body weight two to three hours before a race.

This suggestion of an improved performance encouraged us to undertake the second, and much more extensive, phase of the investigation. The present report will deal primarily with the second phase. Six separate experiments comprised this phase of the investigation. Almost 800 measured performances of swimmers, runners, and weight throwers were obtained. Since each experiment was different from the others in important characteristics, each will be described separately and the results reported separately.

Subjects.—In the first and last experiments swimmers were used as subjects. In the second, third, and fourth runners were used. In the fifth weight throwers and shot putters were used. Except for the subjects in experiment four, all were members of the varsity or freshman teams of large Eastern colleges and universities. All college athletes were tested either during or immediately after their athletic season and so were in competitive physical condition. No experimental trials were run on days when the athletes were competing with athletes from other colleges.

Medicaments.—All subjects in all six experiments received, orally, both a placebo and 14 mg. of amphetamine per 70 kg. of body weight, administered on the double-blind basis. The other necessary controls [1] were also used. As will be shown below, the subjects in five of the experiments received one or more other medicaments (50 and 100 mg. of secobarbital and 7 and 21 mg. of amphetamine) in addition to a placebo and 14 mg. of amphetamine per 70 kg. of body weight. On the first day of the first experiment the medicaments were given in elixir form. Some of the subjects objected to the taste of the elixir. Therefore on the remaining 11 days of that experiment and in all subsequent experiments the medicaments were taken in capsule form. The weight of each capsule was accurate to 0.5 mg. In all experiments except the third, the

---

From the Anaesthesia Laboratory of the Harvard Medical School at the Massachusetts General Hospital.

subjects were given an envelope containing the medicament a day or two before each experimental session. The time at which each capsule was to be taken was written on the envelope containing the capsule. On arriving for the experimental session the subject was asked to inform the experimenter if he had taken the medicament as much as five minutes early or late. In all studies the subjects began their experimental session from two to three hours after taking amphetamine. The time interval was shorter (15, 55, and 60 minutes) for those who took secobarbital. These and other details concerning each of the six experiments are presented below. In describing the various experiments an explanation will be given as to why the experiments were carried out as they were.

Each day before taking the medicament the subject completed a questionnaire giving information about the following items: last night's rest, today's energy level, physical impairments, and degree of eagerness for today's workout. Each day the subject completed an 81-item adjective check list describing his mood and physical condition. The check list was completed once before taking medicament and twice afterward. In addition, after his performance, each subject completed a questionnaire designed to help him evaluate his performance. The results obtained with the questionnaires and check lists will be presented in two subsequent papers.

Method

Experiment 1.—Fifteen collegiate swimmers served as subjects in the first experiment. Each man swam his event twice on each of 12 consecutive experimental days. The second swim began 15 minutes after the beginning of the first and therefore was performed under conditions of fatigue. Three men swam the 100-yd. butterfly, three the 100-yd. free style, three the 200-yd. free style, three the 200-yd. breast stroke, and three the 200-yd. back stroke.

On 4 of the 12 days a subject received 14 mg. of amphetamine per 70 kg. of body weight. On four he received placebo, and on four he received 100 mg. of secobarbital per 70 kg. of body weight. The exploratory phase of our investigation had indicated that a few subjects were able consistently to distinguish the effect of 7 mg. of amphetamine per 70 kg. of body weight from those of a placebo. Since the subjects knew the investigation was one dealing with "pep pills," the possibility existed that a "suggestion effect" was produced whenever the subject noticed any unusual feelings or sensations. In other words, it was possible for the performance to be better on "amphetamine days" than on "placebo days" not because the "pep pills" invigorated the athlete or heightened his motivation but simply because he noticed unusual feelings and sensations and assumed this meant he had been given the "pep pill," expected help from it, and so performed better than usual. The reason for using secobarbital with amphetamine and placebo in five of the six experiments of the second phase of the investigation was to prevent the subject from correctly assuming he had received amphetamine whenever he noticed any unusual feelings or sensations. It was also used in an attempt to clarify the question of whether an amphetamine improvement, when it occurs, is due largely to changes in attitude and psychic state. The added advantage of the two drugs chosen is that earlier work[2] had indicated that both have euphoric power while one is a so-called stimulant and the other a depressant. (The subjects were told only that "pep pills" and placebos were being used.)

The design of this experiment required that each subject receive amphetamine on four days, placebo on four, and secobarbital on four. An attempt was made to control for order-effects which could be produced by progressive changes in level of performance, progressive changes in attitude toward the experiment, and other factors. To control for such effects, the drug sequence was set up so that any given subject would receive one dose of amphetamine, one of placebo, and one of secobarbital during each of the four quarters of his 12 trials. There are six possible ways of ordering three drugs: 123, 132, 231, 213, 312, 321. Each subject was assigned four such sequences, each involving three drugs, giving a total of 12 medicaments. The experimenter collecting the data did not know which drug any particular subject had on any given day. This same general procedure was followed to control for order-effects in the remaining studies.

The 12 experimental days were grouped into 6 competitive days (where the three men in a group raced against each other) and 6 individual days (where each man swam alone, racing against the clock). There were two competitive days and two individual days for each of the three types of medication—amphetamine, secobarbital, and placebo. On one of the individual amphetamine days and on one of the competitive amphetamine days the subject took amphetamine two hours before the beginning of the first swim. On the two remaining amphetamine days he took the medicament three hours before beginning the first swim.

Preliminary studies led us to believe the peak subjective and behavioral effects of 14 mg. of amphetamine occurred between two and three hours after medication, whereas that for 100 mg. of secobarbital was approximately one hour. Consequently the experiment was designed so that the interval between the taking of the active medicament and the beginning of the first swim would be two hours for half of the amphetamine sessions, three hours for the other half, and 55 minutes for all the secobarbital sessions.

On all days a subject took two capsules. The first was taken at either two hours or three hours before the first swim. (Twice under each of the three drugs it was two hours; twice under each it was three.) The second capsule was taken 55 minutes before the first swim on all 12 occasions. On amphetamine days the first capsule contained the amphetamine and the second was a placebo. On placebo days both were placebos. On secobarbital days the first capsule was a placebo and the second contained secobarbital. On placebo days and on secobarbital days the first capsule (which was always a placebo) was taken two hours before the first swim on half of the occasions and three hours before it on the other half.

Each experimental day was organized around six events which were strictly timed. 1. At a specified time (either two or three hours before the first swim) the subject took his first capsule. 2. Fifty-five minutes before the first swim he took his second capsule. 3. Twenty-five minutes before his first swim the subject reported to one of the experimenters and told him if he had failed to take either of the two capsules within five minutes of the time specified. (In no instance did the interval between reported medication time and beginning of first swim deviate from the scheduled interval by more than 15 minutes. The decision was made, without knowledge of drug orderer, not to discard the data which were slightly—5 to 15 minutes—off schedule.) 4. Fifteen minutes later the subject began his warm-up swim, which was timed by a second experimenter to last three to five minutes. 5. The swimmer rested approximately five minutes after warming up and began his first swim exactly 10 minutes after the beginning of the warm-up. 6. Fifteen minutes (plus or minus one minute) after the beginning of his first swim the subject began his second swim.

Each swimmer was timed by two or more clocks. Always one was an ordinary stop watch and one was a 0.01-second electric clock which started automatically at the sound of the gun. (The electric timing device is an invention of Mr. David Collander of Massachusetts Institute of Technology.) One or more additional stop watches were used on approximately half of the races.

Because the electric timing device eliminated the reaction time of starting the stop watch, the electric times were longer (an average of 0.18 second) than the manual times. In coordinating the manual and electric data this difference was taken into account. All time information for each race was examined (without knowledge of which medicament had been given) and the median was accepted as accurate. This same procedure was used in experiment 6. In experiments 2, 3, and 4 only one clock (a manual stop watch) was used for each runner.

The subjects were scheduled in staggered fashion, the first reporting at 4 p. m. and the last reporting at 5:30 p. m. There were a few deviations from this plan due to scheduling problems. However no subject ever reported earlier than 3 or later than 6 p. m.

The cooperation on the part of the subjects in this experiment was exceptionally good. They usually reported for the experiment about five minutes before they were scheduled to arrive. In the total 180 sessions no more than five began late, and in these instances the lateness was usually between 5 and 15 minutes.

Experiment 2.—Nine collegiate track men served as subjects in experiment 2. Three ran 600 yd., three ran 1,000 yd., and three ran one mile. Each man ran these distances only once each experimental day. The sessions were separated by at least one day. Experimental sessions were never carried out either on the day of a meet with another school or on the day preceding such a meet. The runs occurred on an indoor track with a cinder surface. The men ran in competitive groups of three, except on two occasions when scheduling problems reduced the size of a group to two. All races occurred between 4:30 and 5:15 p. m.

The experimental design called for nine runs from each subject, three sessions in which the subject would be medicated with 14 mg. of amphetamine per 70 kg. of body weight, three with 50 mg. of secobarbital per 70 kg., and three with placebo. Due to illness one subject completed only three runs and so contributed only one run under each of the three medication conditions. Following the procedure outlined in experiment 1, the secobarbital was taken one hour before running and the amphetamine was taken two hours before running.

In this experiment and in the subsequent ones the barbiturate dosage was only half that used in experiment 1. As mentioned above, the barbiturate was used to prevent the subject from correctly assuming he had received amphetamine whenever he thought he perceived drug-effects. The 100-mg. dosage, used in experiment 1, was so potent that subjects occasionally said such things as the following to the experimenter: "I feel sort of dopey. I think I got a sleeping pill today." To reduce the obviousness of its effects, the secobarbital dosage was changed to 50 mg. per 70 kg. in the present experiment and in the three subsequent ones where secobarbital was used.

Analysis of the data of experiment 2 was complicated by the fact that on the day of session 8 the track was filled with holes. Session 8 occurred after the track season was over and the baseball players had begun practicing in the indoor track "cage." Due to an oversight the track had not been rolled before the beginning of this session, and baseball practice had left it in bad condition. The amount of impairment produced by the poor track conditions was assessed by obtaining for each subject the difference between his time on session 8 and his mean time on the other two sessions when he ran under the same type of medication as that given him on session 8. In all instances the time for session 8 was greater. The average difference for the group was 12.6 seconds. The average percent difference was 6.7. The "t" value for the mean difference of 6.7 was 3.41, which is beyond the 0.02 level of significance. The results of experiment 2 are reported both including and excluding the data obtained on session 8.

Experiment 3.—In experiment 3 eight collegiate track men ran once on each of six experimental days. They ran in competitive groups of two or three on an outdoor wooden track. Three men ran a mile. Three ran 600 yd. Two ran 440 yd. The subjects were given 14 mg. of amphetamine per 70 kg. on two occasions, with 50 mg. of secobarbital per 70 kg. on two and with placebo on two. Each day the subject took two casules. The first capsule was taken two hours and the second one hour before running. On amphetamine days the first capsule contained amphetamine and the second was a placebo. On the secobarbital days the second capsule contained the active agent. Both capsules were inactive on the placebo days. All runs took place between 2 and 4:30 p.m.

The original design of this experiment called for 12 runs from each subject. However only six were completed by the time the wooden track was removed for spring baseball practice. Our aim had been to have an interval of at least one day between experimental sessions. However in about one-third of the cases this was not possible because of scheduling problems. The cooperation of these subjects was poorer than that of the other groups studied. Their races were frequently 10 to 20 minutes off schedule. There were numerous cancellations and changes of schedule. Interpretation of the results was further complicated by the fact that the subjects ran on an outdoor track during winter. The temperature and wind velocity varied considerably and influenced running times.

Experiment 4.—The nine subjects participating in experiment 4 were marathon runners preparing for the Boston Athletic Association Marathon and other long-distance races. They were tested during the two months preceding the marathon, which occurred on April 20.

These subjects were different from those in the other five experiments primarily by virtue of age. The age range was 22 to 41 years, with a median of 33 years. Four of these men had attended college. All of them were experienced runners. Most had been running for several years. Seven had won Amateur Athletic Union–sponsored long-distance races on one or more occasions. The other two had been among the first five to finish in one or more such races.

The original design called for 12 runs from each man, three times after the placebo had been given, three times with 50 mg. of secobarbital per 70 kg., twice with 7 mg. of amphetamine per 70 kg., and twice with 14 mg. and twice with 21 mg. amphetamine per 70 kg. Because of weather difficulties and injuries only three of the runners completed all 12 runs. Two completed 8, one 10, one 9, one 6, and one 5 runs.

Any given subject in this experiment ran the same distance and the same course each day. However, the various subjects ran different courses. The shortest course was approximately 4.5 miles and the longest approximately 12.7 miles. Each subject timed himself.

Each day a subject took two capsules. He took the first capsule two hours and the second 15 minutes before beginning the race. As in the preceding experiments amphetamine medicaments were put in the first capsule, secobarbital in the second, and placebos in both. The various subjects ran for different lengths of time, depending on the length of their course and their running speed. The shortest running time occurred on a 4.7-mile course (24 minutes and 10.5 seconds) and the longest running time occurred on the 12.7-mile course (92 minutes and 20 seconds). The time interval between taking the second capsule and starting the race was shorter (15 minutes) in this experiment than in the others. This was done primarily for reasons of safety. (Several of the subjects drove automobiles to the starting point of their courses. We did not want subjects who were unprepared for the possible effects of mental clouding and sedation to begin experiencing these effects while driving to their courses.)

Before beginning the experiment a subject was told the reason for the study and was told that extraneous factors such as weather conditions and his physical condition could influence the results of his time-trials. He was asked to control as well as possible all such factors and, in particular, not to take the medicament when the weather was bad. The subject filled in a questionnaire after each race, indicating all factors which might have influenced his running time that day.

In all experiments we pointed out to the subject that his role was that of experimenter as well as subject. An attempt was made to inspire all subjects to be meticulously careful and honest in carrying out their responsibilities. An especially strong effort was made in this respect in the present experiment because all measured performances of the marathon runners were carried out in the absence of the experimenter. The subject was given 12 packages, each containing the medicament and performance-analysis materials for one trial. He was asked to run the same course every session, not to run when the weather was bad, and not to run when his physical condition was impaired to an extent which might affect his running time. In the entire 82 runs of this experiment only 3 were discarded because of violation of these controls. One session was discarded because subject 4 altered his course on that day. (Snow began to fall after the subject had begun his run. In an attempt to compensate for this, he shortened his course.) On another occasion subject 5 (whose 6.8-mile course was an approximately straight line between his home and his place of work) discovered on beginning his race that he had to face a 30-mile per hour headwind the entire distance. On this occasion his time was 49.30 (49 minutes and 30 seconds). In his remaining 11 trials there was a 2.75-minute range (from 40:30 to 43:15). The wind caused his time to fall 6.25 minutes outside that range. On the third discarded occasion a still different runner (subject 7) ran an experimental session the day after he had competed in a 30-km. (18.64-mile) Amateur Athletic Union race. He began the race reporting sore feet as a physical impairment. He ran his 4.7-mile course that day in 33 minutes and 52 seconds. As in the case of the man running against the headwind, the time just reported was grossly out of line with the remaining ones. On this man's remaining eight trials his best time was 24:10.5 and his worst was 27:15 (a range of 3 minutes and 4.5 seconds). His "sore feet" time of 33:52 was over six minutes outside the range of his other eight races.

Experiment 5.—Thirteen collegiate weight-throwers and shot-putters served as subjects in experiment 5. Nine threw the 35-lb. weight. Four put the 16-lb. shot. All were members of varsity or freshmen teams. (Although shot-putters are sometimes called weight-throwers, the present report will distinguish between the two groups by calling the nine who threw the 35-lb. weight weight-throwers and calling the four who put the 15-lb. shot shot-putters.) All experimental sessions were carried out in a heated indoor track cage.

* Dosages were 11 mg. of amphetamine sulfate per 70 kg. of body weight and 100 mg. of secobarbital per 70 kg. of body weight.

† $\overline{P}$= mean placebo time for each subject. $\overline{A}$=mean amphetamine time for each subject. $\overline{S}$=mean secobarbital time for each subject. $\overline{P}-\overline{A}$ indicates change in performance under amphetamine: + indicates improvement: — indicates impairment. The per cent change scores listed under $\frac{\overline{P}-\overline{A}}{\overline{P}}$, % were obtained with the formula $(\frac{\overline{P}-\overline{A}}{\overline{P}})$ (100).

Both weight-throwers and shot-putters threw 15 to 25 times each day. (The subjects were told that their first three throws would be considered warm-up throws and would not be counted. In analyzing the data the decision was made to eliminate the first five rather than the first three because the fourth and fifth throws were in general below the mean of the remaining throws. This decision was made without knowledge of the drug administered to a given subject on a given day.) Chalk lines were drawn every 5 ft. within the throwing range. An experimenter was stationed about 30 ft. from the point at which the weight was expected to fall. When it landed, the experimenter estimated its distance by relating the identation made in the ground at the point of contact to the system of chalk lines. (Time limitations prevented tape measurement.) After each throw the subject walked to the point where his throw had landed and then gave his own distance-estimate to the experimenter. In general the discrepancies between estimates made by the experimenter and those made by subjects were less than one foot. The average for all subjects for all sessions was 0.41 ft.

The design called for 12 sessions, four with 14 mg. of amphetamine per 70 kg. of body weight, four with 50 mg. secobarbital per 70 kg., and four with placebo. Only 7 of the 13 men completed all 12 sessions. Two were there for 10, one for 6, one for 5, and two for 4 sessions. The two subjects contributing only four sessions (subjects 7 and 8) (tables 8 and 9) were 35-lb. weight-throwers who were somewhat uninterested in the experiment. In general their cooperation was poor. Five of their eight sessions were ones on which they either reported late or failed to take their medicament on time. The subject contributing five sessions (subject 9) was a freshman who changed his style after the third session, adding another body turn. The data contributed by the three men just mentioned are suspect as well as sparse. Consequently the weight-throwing analyses have been done both including and excluding these three subjects. As in the earlier experiments the subjects took two capsules each day, one or both of which contained placebos. Amphetamine was taken two hours and secobarbital one hour before the session began.

Although no subject contributed more than 12 sessions the study lasted a total of 15 days because of missed sessions and make-ups. The experimental sessions began at 4:30 p.m. on each of the first nine days of the study. Because of unavailability of space they began at 7:30 p.m. on the final six days. During the latter sessions the subjects were instructed to take their first capsule at 5:45 p.m., eat dinner at 6:15, take their second capsule at 6:45, and report for the experiment at 7:30. (The effect of amphetamine on performance was found to be somewhat similar in the afternoon (mean improvement = 4.84%) and in the evening (mean improvement = 6.29%.)

Experiment 6.–Sixteen swimmers served in this experiment. Thirteen of them had previously been subjects in experiment 1. Three were new. There were several ways in which this experiment differed from the first one. There were 6 sessions rather than 12. On three days a subject received 14 mg. of amphetamine; on three he received a placebo. No secobarbital was used. The drug order was random with the two restrictions that (1) no subject would receive the same medicament three times consecutively and (2) no subject would receive the same medicament on either the first and second or the fifth and sixth sessions. All capsules were taken two hours before the race. With a few exceptions an interval of one day intervened between adjacent experimental sessions. Experiment 1, on the other hand, had been run on consecutive days. Experiment 6 was begun two days after the final competitive meet of the year. Experiment 1 had been carried out in the early part of the season. In the present experiment each subject swam only once each day rather than twice. This was done to encourage the subjects to give an "all out" effort. They did not have to save themselves for a second race.

The major difference between experiments 1 and 6 was that in the sixth we tried to guarantee maximum effort from each subject on all swims. (We had asked for maximum effort in all experiments. However, in experiments 1, 2, and 3 we compared the experimental times with those achieved in meets with other schools and found the experimental times to be slower for most subjects than the meet times. Interestingly, this was not the case with the weight-throwers and shot-putters of experiment 5. The longest experimental throws were, in general, as far as the longest meet throws.) To achieve an experimental situation which would stimulate maximum effort and approximate the psychological atmosphere of a competition with another college the following steps were taken. First, the subjects were called together for a meeting before the experiment began. At this meeting it was explained that the sole purpose of the experiment was to test the pep pills under conditions which simulated the school competition situation. We explained that our investigation could not be considered complete until we knew whether the pep pills were effective under conditions of maximum motivation and 100% effort. (No information was given concerning the results of the previous experiments.)

Second, the race times each swimmer had achieved in the final three to five competition swims of the season were collected from the coach and the median of these times was computed for each subject. At the preexperimental meeting each subject was given his median competition time and was told that this was the goal he was to attempt to match in the experimental swims. The subjects were told that each man whose median experimental time equaled or beat his median competition time would be treated to a steak dinner, where he could order anything he wanted up to $7.50. Furthermore, they were told the whole group would win the dinner if as many as half of the men won.

Third, the swimmers were asked to cheer on their teammates just as they customarily did during competition with other schools. Throughout the experiment the swimmers did this. Indeed, several observers remarked that on some experimental sessions the enthusiasm and excitement were greater than that seen at meets with other schools.

Several of the swimmers made their "steak" times on both the first and second experimental days. This raised the possibility that certain of the subjects might win their steaks on the first four swims and then relax on the last two. To avoid this a new element was added to the experiment at the beginning of the third day. The subjects were told that any swimmer who made his "steak" time on five out of six occasions would be treated to an extra steak dinner on some evening subsequent to the first.

In general, the attempt to obtain maximum performance was successful. Nine of the 16 swimmers broke their "steak" times on at least three out of six occasions. Two broke their lifetime records. Five more came within 0.3 second of their lifetime records. Forty-seven of the 93 swims reached the "steak" time criterion. One might wonder why the "steak" time incentive was so effective with these subjects. This incentive was chosen because we discovered in talking with the subjects after the first experiment that winning a steak dinner appeared to have symbolic significance for the boys. On various past occasions certain ones of them had been given steak dinner incentives by their coaches. In these instances the steak dinner had meant much more than its monetary equivalent. Our experimental "steak" time arrangement was selected in an effort to tap this previously established symbolic reward system.

Fifteen of the 16 swimmers completed their six scheduled swims. One (subject 13) became ill and was able to complete only three (table 11). Another (subject 14) had a series of misfortunes. He missed four regularly scheduled sessions, which he subsequently made up. Once he caught the "flu." Once he received a third degree burn on his arm. In addition to missing four regular sessions he performed four of his swims under handicapped conditions. Once he swam still feeling weak from the "flu." Twice he swam with a bandage covering the burn on his arm and reported that the water caused pain at the point of the burn. On still another occasion he received an allergy shot before swimming and reported that this had produced swelling, stiffness, and pain in his arm. The range between his best and worst time was 11.2 seconds. This is more than five times as great as the mean range for the remaining 15 subjects. The swimming analyses reported in the next section were performed both including and excluding these two swimmers.

* The 72 Md values (mean difference values) give a more detailed breakdown of information presented in table 2. Average magnitude and average per cent differences between amphetamine time and placebo time for the three groups (100-yd., 200-yd., and combine) are presented separately for individual and competition conditions. Within each of those conditions there is a further breakdown for the 2-hr. and 3-hr. intervals. For the most detailed breakdown, each Md score is based on only one amphetamine and one placebo time for each subject.

Four of the 16 subjects swam the 200-yd. breast stroke, 3 swam the 200-yd. back stroke, 3 the 200-yd. free style, 3 the 100-yd. butterfly, and 3 the 100-yd. free style. All races occurred between 4:30 and 6:30 p.m. Eleven of the subjects swam in groups of two or three. Five swam alone. All 16 subjects were combined into a single group in the analyses because examination of the comparative swimming times under the effects of amphetamine and placebo indicated that the 5 men who swam alone were not affected differently by amphetamine than were the 11 who swam in groups. Presumably this was because the subjects swam with maximum or near maximum motivation whether swimming alone or in groups. The results of this experiment are reported in table 11.

As in experiment 1, the cooperation of subjects in this experiment was remarkable. In the entire 96 occasions, subjects reported more than five minutes late only three times. On two occasions subjects reported taking medicaments late; one subject took one of his medicaments 10 minutes late and another was 15 minutes late in taking one of his.

Data Collected in Phase I.—Our investigation of the effects of pep pills on athletes was carried out in two phases. The first provided a broad exploratory coverage of the problem. We studied several different dose levels using various time intervals between medication and performance. One dose level (7 mg. per 70 kg.) was studied in a sufficient number of subjects (20) to warrant inclusion in this report. Those data are presented in the section on results, after presentation of the more substantial and extensive results obtained in phase 2.

The work done in the first phase was exploratory. Different subjects were studied differently. In presenting the results obtained with each subject a tabular summary of the more important methodological details will be given.

RESULTS

Experiment 1.—Experiment 1 was the most extensive and intricate of the six experiments described in the preceding section. It provided 360 measured performances by 100-yd. and 200-yd. swimmers. The results obtained with each of the 15 swimmers in the first experiment are presented in table 1. Each subject swam four times under each of three drug conditions: placebo, amphetamine (14 mg. per 70 kg. of body weight), and secobarbital (100 mg. per 70 kg.). Each subject's mean time for the first (rested condition) swim on the four placebo sessions and his corresponding mean time for amphetamine and secobarbital sessions are shown; times for the second (fatigued) swims under influence of placebo, amphetamine, and secobarbital, respectively, are also shown. (The results of the statistical analyses of the data presented in table 1 are shown in tables 2 and 4.)

Table 1 shows the difference between each subject's mean placebo time and his mean amphetamine time for the first swim. Of the 15 subjects, all but one have plus scores, indicating that they swam faster under influence of amphetamine than of placebo. The mean improvement for the 15 subjects taken as a group was 1.26 seconds. As shown in table 2, this improvement is very significant, statistically. When evaluated with the "t" test for correlated means it yields a "t" value of 4.17, which is beyond the 0.001 level of significance using a two-tailed test.

Column 5 of table 1 presents the comparative performance under influence of amphetamine and placebo on the first swim in a different way. Here the difference between a subject's mean placebo score and his mean amphetamine score is expressed as a percentage of his mean placebo score. Table 2 shows that the 15 swimmers taken as a group obtained a mean improvement of 1.16% under amphetamine. This average improvement yields a "t" of 3.82, which is beyond the 0.01 level of significance.

Column 6 of table 1 shows the comparative swimming time under influence of placebo and secobarbital. Fourteen of the 15 subjects were impaired by secobarbital. The group had an average impairment of 2.18 seconds. The corresponding percentage of impairment for the group was 1.9%. The "t" values for these mean differences are shown in table 4.

Column 11 of table 1 presents the comparative effects of amphetamine and placebo on the second swim. The performance of 10 of the 15 subjects was improved by amphetamine. However, the average

* Symbols are defined in earlier tables. The Md scores are based on the $\overline{P}$-$\overline{S}$ and $\frac{\overline{P}\text{-}\overline{S}}{\overline{P}}$, % scores presented in table 1.

improvement for the group was only 0.29 second. The corresponding average percentage improvement was 0.59% (table 2).

Column 13 shows that 13 of the 15 subjects were impaired by secobarbital on the second swim. The average impairment for the group was 1.55 seconds ("t"=3.80; $p<0.01$). The corresponding impairment was 1.49% ("t"=3.16; $p<0.01$) (table 4).

Table 1 presents the results of the statistical comparisons of placebo versus amphetamine (14 mg. per 70 kg.) for each of three groups: the six 100-yd. men, the nine 200-yd. men, and the 15 swimmers combined. The results shown in table 2 were arrived at using the "t" test for correlated means. The "t" test values and their associated two-tailed probability values are reported both for magnitude of difference (mean placebo minus mean amphetamine) and for percentage of difference (mean placebo minus mean amphetamine/mean placebo). In these comparisons there is no breakdown for the competitive versus individual conditions or for the 2-hour versus 3-hour conditions. (Such a breakdown is given, however, in table 3).

[*] Symbols defined in table 2; scores based on those in table 1.

As shown in table 2, amphetamine produced statistically significant improvement for both the 100-yd. swimmers and the 200-yd. swimmers during the first swim (rested condition) but produced significant improvement for only the 100-yd. men on the second swim (fatigued condition).

Table 3 shows the comparative effects of placebo and amphetamine (14 mg./70 kg.) on swimming times when the subjects swam alone (racing against the clock) and when they swam in competition (racing against each other). This table presents a further breakdown (within the individual condition and within the competition condition) of the effects of amphetamine when taken two hours before the first swim and when taken three hours before the first swim. The amphetamine versus placebo comparisons in table 3 give some indication that the amphetamine effects may have been slightly greater at three hours than at two hours after medication, especially on the second swim comparisons. However this tendency is not consistent enough to be more than suggestive. Consequently the description of results in the next two paragraphs will be limited to the comparisons combining the data obtained at the two time points.

For the first swim (rested condition) amphetamine produced improvement in both 100-yd. and 200-yd. men, both when the men swam individually and when they swam in competition. Swimming individually, the mean improvement scores were 1.24 seconds., 1.95 seconds, and 1.67 seconds for the 100-yd., 200-yd., and combined groups respectively. All three improvements were beyond the 0.10 level of significance. The corresponding improvement scores were 1.81%, 1.19%, and 1.44% (all beyond the 0.10 level of significance). When the subjects swam competitively the amphetamine improvement was not as great as that found when the subjects swam individually. The 10-yd. men obtained an improvement of 0.96 seconds. The 200-yd. men improved 0.77 seconds. The combined group improved 0.84 seconds. The corresponding improvement scores were 1.37%, 0.54%, and 0.87%. (See table 3 for "t" values and significance levels.) Although the 15 subjects obtained a greater mean difference between amphetamine and placebo when swimming individually than when swimming competitively, this difference did not reach the 0.20 level of significance.

On the second swim (fatigued condition) there was an interesting difference between the 100-yd. and 200-yd. swimmers under the competition condition. Whereas the 100-yd. men swam 0.66 seconds faster under the influence of amphetamine than under placebo ("t"=4.01; $p<0.02$) the 200-yd. men swam 2.17 seconds slower under influence of amphetamine ("t"=3.23; $p<0.02$). On the other hand, both groups of swimmers obtained an amphetamine improvement when swimming individually, although the improvement for the 200-yd. men was slight.

Table 4 presents information concerning the comparative effects of secobarbital and placebo, under rested and fatigued conditions, with a breakdown for individual and competitive conditions. On the first swim the 200-yd. men showed about the same impairment when swimming individually (2.87 seconds and 1.99%) as when swimming competitively (2.90 seconds and 1.92%). The 100-yd. men showed more impairment when swimming individually (1.41 seconds and 2.30%) than when swimming competitively (0.81 seconds and 1.32%).

On the second swim the 100-yd. and 200-yd. men showed an interesting difference in secobarbital effect. The 100-yd. men were impaired more than twice as much when swimming individually than when swimming competitively (2.20 seconds as opposed to 0.96 seconds), whereas the 200-yd. men showed just the reverse. They were impaired 0.97 seconds when swimming individually and 2.07 seconds when swimming competitively. Both with respect to magnitude and percent effect, table 4 shows that on the second swim 100-yd. men were *impaired to a statistically significant extent* when swimming individually (but not when swimming competitively) while the 200-yd. men were impaired significantly when swimming competitively but not when swimming individually.

The 15 swimmers comprised five groups of three men each: 100-yd. free style, 100-yd. butterfly, 200-yd. free style, 200-yd. back stroke, and 200-yd. breast stroke. Table 5 shows that all five groups swam faster under influence of amphetamine than under placebo on the first swim. On the second swim the two groups of 100-yd. men and the 200-yd. free style group swam faster under influence of amphetamine than placebo but the 200-yd. breast stroke and 200-yd. back stroke groups swam slower under influence of amphetamine than placebo. On both first and second swims all five groups showed impairment under secobarbital (table 5).

Subject 9 increased the variability of the group greatly. Consequently the "t" values are low in spite of the fact that eight of the nine subjects improved during use of amphetamine.

As mentioned before, session 8 was carried out under atypical conditions. The statistical analyses were performed both including and excluding that session. The right half of table 6 presents the results obtained excluding session 8. The average improvement under amphetamine was 6.37 seconds ("t"=2.23; $p<0.10$). The corresponding improvement was 3.17% ("t"=2.46; $p<0.05$).

Both the analyses including session 8 and those excluding it show that the subjects ran slightly faster under secobarbital (50 mg. per 70 kg.) than under placebo. However, none of those comparisons reached the 0.20 level of significance.

Experiment 3.—Five of the eight subjects in experiment 3 ran faster under influence of amphetamine than placebo; three ran slower. Considered as a group, the subjects had an average amphetamine time which was 1.08 seconds faster than that for placebo. The corresponding percentage difference was 0.89%. However, neither of these comparisons reached the 0.20 level of significance. We believe this lack of significance was due partly to uncontrolled weather variables. (As mentioned before, this experiment was carried out during the winter on an outdoor track. The temperature varied from 25 to 69 F. The wind velocity varied from 8 to 23 miles per hour. To assess the effect of variations in temperature on running time, each subject's score on the warmest amphetamine day was subtracted from his score on the coldest amphetamine day; then the same was done for his two placebo days and two secobarbital days. The mean of these three difference scores was then obtained. The resulting score showed the effect of temperature, with the drug-effect controlled. Seven of the eight subjects ran faster on the warm days than on the cold days. The mean difference for the group was 2.89 seconds. A comparable analysis was performed to evaluate the

* Symbols defined in earlier tables.

Experiment 2.—Table 6 presents the results obtained with the nine runners who performed on an indoor track. The mean performance times under the influence of placebo, amphetamine (14 mg. per 70 kg.), and secobarbital (50 mg. per 70 kg.) are shown in columns 1, 2, and 3 respectively. Column 4 shows the difference between each subject's mean placebo time and his mean amphetamine time. Column 5 expresses that difference as a percent of the mean placebo time. Columns 6 and 7 show the corresponding magnitude and per cent comparisons for placebo versus secobarbital. The results of the statistical evaluations of these scores appear at the bottom of the table.

Column 4 shows that eight of the nine runners performed faster under influence of amphetamine than under placebo. The mean difference for the amphetamine-placebo scores is 4.24 seconds. The mean difference is 2.21%. These two mean differences yield "t" values of 1.30 and 1.91 respectively.

effect of variations in wind velocity. Seven of the eight subjects ran faster on the less windy days. The mean difference for the group was 2.20 seconds.)

Experiment 4.—Table 7 presents the results obtained with the nine marathon runners performing under placebo, secobarbital (50 mg. per 70 kg.), and three different dosages of amphetamine (7, 14, and 21 mg. per 70 kg. of body weight). Data obtained under the three dosage levels of amphetamine were combined in the comparisons shown in table 7. Six of the subjects ran faster under influence of amphetamine than placebo; three ran slower. Considered as a group the subjects ran an average of 24.12 seconds faster under influence of amphetamine than placebo ("t"=2.13; $p<0.10$). The mean difference was 1.07% ("t"=1.72; $p<0.20$).

As in experiment 3, the performances of experiment 4 occurred out of doors during late winter. Weather variable added to the variability of the date and tended to reduce the statistical significance of the improvement shown under amphetamine by the group.

[*] Dosages of 7, 14, and 21 mg. of amphetamine per 70 kg. of body weight and 50 mg. of secobarbital per 70 kg. of body weight were given.

[†] The three amphetamine dose levels were combined in obtaining the $\bar{A}$ values.

There were reasons for questioning the validity of the data contributed by all three of the subjects who ran faster under influence of placebo than amphetamine; however, the decision was made to retain their data. Subject 6 had only one placebo session. Subject 4 indicated on his performance analyses that 9 of his 12 performances (75%) were not "all-out" efforts. The corresponding average for the remaining eight subjects was 15%. All subjects had been asked to make each effort an "all-out" one. In general, subject 4 did not appear to grasp the concept of a controlled experiment. He was the subject who altered his course on one occasion. The result of one of his races was recorded in the wrong place. Other indications of failure to meet the requirements of the experiment were also found in his data.

Both the fastest time and slowest time for subject 2 occurred under the 21 mg. per 70 kg. dose of amphetamine. That slow amphetamine race occurred the day after the subject had "run himself into the ground" in a hard 15-mile race wearing 10 lb. of clothing. The runner's written comments made after the race follow:

> First I would like to say that I was wearing 10 pounds of clothing (my boots alone weighing 3½ lb.) in my 15 miles work out last night in which 'I ran myself into the ground.' This was the hardest work-out I'd had in months. Needless to say, I was very tired today. I feel therefore that had I done 6 miles (not too hard) instead of 15 miles last night, a time equal to or better than my best time of 33:25 would not have been unreasonable. I was thinking in terms of a 35 minutes-something, work-out before my first medication! And yet, after a ½ hr. sleep between capsules and just after my second, my mood and outlook changed substantially, so I estimated 34:40. However, while running my first 100 yards I wished I'd estimated even something around 36:00 minutes—my legs just wouldn't go and I felt very tired. But since I feel it a responsibility to do my very best in order to make these experiments worth while, I pushed myself hard and worked my arms harder than usual. I soon established a better racing pace but it was just one hell of a grind *all* the way. My time was 34:08,7! I was amazed that I could force myself so much today. My legs felt light and loose afterwards and I enjoyed a 2 mile jog. I have had a tingling and chilled sensation of my body since the run. As a summary, I feel this was the most substantial mental and physical change I have ever experienced in such a short period of time.

To compare different dose levels, it was planned that each subject would run twice under each of three dose levels of amphetamine. Due to illness and adverse weather, only three subjects completed all sessions. Of the sessions run, three were discarded as mentioned under "method." Four of the nine subjects made only one run under the 7-mg. dose, five made only one run under the 14-mg. dose, and five made only one run under the 21-mg. dose. Furthermore, 10 of the sessions retained were performed under conditions of moderate physical impairment or weather adversity. These considerations require cautious interpretation of the data. The subjects ran faster on the average under 14-mg. doses of amphetamine than under 7-mg. doses, and still faster under the 21-mg. dose, but the factors mentioned cast doubt on the accuracy of the differences observed in results after use of the three dose levels. The subjects ran 0.06% slower, 0.30% faster, and 2.54% faster under the 7-mg., 14-mg., and 21-mg. doses, respectively, than after taking the placebo. The first two comparisons were not significant at the 0.20 level. The third was significant beyond the 0.10 level. Because of the uncontrolled factors mentioned and because half the subjects had a given dose level only once, the comparisons at the three separate dose levels were less stable than the comparison combining all three. The standard error for the combined analysis was 0.62%, while those for the comparisons based on 7-mg., 14-mg., and 21-mg. dose performances considered separately were 0.89%, 0.83%, and 1.21% respectively.

Experiments 2, 3, and 4 Combined.—In all three experiments using runners as subjects, the groups ran faster under the influence of amphetamine than under placebo. The man improvement scores were 2.21%, 0.89%, and 1.07% for experiments 2, 3, and 4 respectively. This is slightly higher than the mean improvement found with the swimmers of experiment 1. In spite of this the statistical evaluations of the data obtained with the runners were in no case as convincing as those based on the data obtained with the swimmers. This was due in part to factors already mentioned which increased the instability of the data.

The data are stabilized somewhat by combining the three experiments. (The standard error for the analysis combining the percentage scores of experiments 2, 3, and 4 is only 0.60%; those for experiments 2, 3, and 4, considered individually, are 1.34%, 1.23%, and 0.62% respectively.) Since the various subjects ran various distances (440 yards to 12.7 miles) the combined analysis was performed on the percent scores ($\overline{P}$-$\overline{A}$/$\overline{P}$%) only. Combining the three groups yields a mean improvement under amphetamine of 1.40%. The "t" value for this combined analysis is 2.42, which almost reaches the 0.02 level of significance. A further combined analysis was carried out excluding session 8 in experiment 2. This produced a mean difference of 1.74% ("t"=2.75; p<0.02).

† Symbols are defined in earlier tables

‡ *Weight-throwers whose data we judged to be unreliable, before determining which drugs were given on which days (see text).*

Each man threw approximately 15 to 25 times each day. Each day a subject's maximum and mean throws were determined. The mean of each subject's maximum throws under each drug condition appears in table 8. Column 1 presents the mean of each subject's maximum throws for his placebo days. Columns 2 and 3 show the means of the maximum throws for the amphetamine and secobarbital days respectively. Column 4 shows the comparison of each subject's maximum score under influence of amphetamine with his maximum score under placebo. Column 5 expresses the amphetamine—placebo difference as a percentage of the placebo score.

Table 9 presents similar information concerning the effects of amphetamine and secobarbital on the mean distances thrown. Table 10 presents the results of statistical analyses of the data reported in tables 8 and 9.

Under "Method" we mentioned that the weight-throwing analyses were carried out both including and excluding the results obtained with three subjects whose data were sparse and in our judgment unreliable. Table 10 gives the results of four separate evaluations of each type of score: the first is based on the data of the six 35-lb. weight-throwers who contributed six or more sessions; the second is based on the data of the four 16-lb. shot-putters; the third combines these two groups; the fourth is based on the data of all 13 subjects, including the three subjects whose data are questionable.

Table 10 shows that all amphetamine *versus* placebo analyses based on the total group of 13 are significant beyond the 0.10 level. The ana exclude the three subjects mentioned above yield even clearer demonstrations of an amphetamine effect. (All are significant beyond the 0.01 level.)

With regard to the maximum distance scores, the six weight-throwers and four shot-putters obtained average improvement scores of 2.50 ft. and 1.48 ft. respectively, under influence of amphetamine. The average improvement for the group of 10 was 2.09 ft. This group effect yields a "t" of 5.84, which is significant beyond the 0.001 level. The corresponding improvement scores for these three groups were 5.41%, 3.30%, and 4.56%.

The results obtained with the evaluation of mean distance scores are very similar to those obtained when the comparisons were made on the basis of maximum distance scores. Under amphetamine (14 mg. per 70 kg.) the 6 weight-throwers obtained an average improvement of 1.99 ft., the 4 shot-putters improved 1.78 ft., and the total group of 10 improved 1.91 ft. This average improvement of 1.91 ft. yields a "t" of 4.10, which is beyond the 0.01 level of significance. The corresponding average improvement scores are 4.53%, 4.19%, and 4.39% for the weight-throwers, shot-putters and combined groups respectively. Both with respect to maximum scores and mean scores the six 35-lb. weight-throwers obtained statistically significant improvement ($p<0.10$) under influence of secobarbital. The four 16-lb. shot-putters obtained impairment. The total group of 10 showed improvement for both maximum and mean scores but neither comparison reached the 0.20 level of significance.

Experiment 6.—Table 11 shows the average swimming time of each of the 16 swimmers under influence amphetamine and placebo. It also shows each subject's goal ("steak time"), the difference between his mean time under placebo and his mean time under amphetemine, and the percent improvement or impairment produced by amphetamine. Eleven of the 16 subjects swam faster under influence of amphetamine than placebo. Table 12 pre[illegible] average magnitude and average percentage [illegible] for the 6 100-yd. swimmers, for the 10 200-yd. swimmers, and for the 16 swimmers taken as a group. It also presents the results of the statistical evaluations of these comparisons. The average amphetamine improvement for the 6 100-yd. swimmers was 0.56 second; that for the 10 200 yd. swimmers was 0.68 second; that for the 16 men considered as a single group was 0.63 second. The total group "t" yields a mean difference of 0.63 second, of 2.14 which is significant beyond the 0.05 level. The mean improvement scores for the 6 100-yd. men, the 10 200-yd. men and the total group of 16 were 0.95%, 0.45%, and 0.64% respectively. The "t" value for the 0.64% improvement shown by the total group was 2.49, with a corresponding two-tailed probability values of <0.10, beyond the 0.05 level.

As mentioned before, two of the swimmers contributed data which we judged (before the drugs administered were known in the given cases) to be less reliable than that of the other 14 subjects. Eliminating these two subjects raised the mean improvement from 0.63 second to 0.71 second and changed the "t" value from 2.14 to 2.13. The mean improvement was raised from 0.64% to 0.72% and the "t" value changed from 2.49 to 2.50.

Table 13 presents the average magnitude and average percentage effects for each of the five subgroups of subjects. One man in each subgroup swam faster under the influence of placebo than of amphetamine. However each of the five subgroups, considered as a unit, swam faster under influence of amphetamine.

The sixth session was one in which the motivation and attitude of certain of the subjects may have been different from that of earlier sessions. Whether the whole group won steak dinners depended on the final performance of two of the subjects. On the other hand, five of the subjects had reached the "steak time" criterion on each of their first five performances and came to the sixth session knowing they had won their two steak dinners and could win no more. A final analysis was performed eliminating session 6. The results were very similar to those

obtained including session 6. The total group of 16 subjects swam an average of 0.67 second faster under influence of amphetamine than placebo ("t"=1.86; $p<0.10$). The corresponding improvement was 0.53% ("t"=1.89; $p<0.10$).

Data from Phase 1.—Fourteen swimmers and six runners were studied in phase 1 while medicated with placebo or 7 mg. of amphetamine per 70 kg. body weight. The results obtained with each subject are presented in table 14. That table also indicates the event performed by each subject, the number of placebo and amphetamine medicaments used, the time interval between taking the medicament and beginning the performance, and whether the event was performed individually or competitively. Since a wide range of distances is represented among these subjects (50 yd. to 440 yd. for the swimmers, and 440 yd. to two miles for the runners) we carried out statistical tests only on the percentage improvement or impairment scores shown in the last column on the right. Eleven of the 14 swimmers swam faster under influence of amphetamine than placebo. The mean improvement for the swimmers taken as a group was 0.53%. This group improvement yields a "t" value of 2.04, which is beyond the 0.10 level of significance using a two-tailed test. The nine subjects who swam individually contributed considerably more to the group improvement than did those five who swam in competition.

Two of the six runners ran faster under influence of amphetamine than placebo. Four ran slower. The average impairment was 0.40% and did not reach the 0.20 level of significance.

* Subjects 3, 4, 12, 13, and 14 were the five who swam alone. The others swam in competition—groups of two or three men.

Comment

Problems of Control.—Detailed and perhaps tedious descriptions have been given of the attempts made in the various experiments to control all factors which might influence the comparisons of amphetamine and placebo. Where weather variables, lack of interest, or cooperation on the part of subjects or other factors appeared to influence the results, we have so indicated. The reader has been burdened with these details because we believe they are essential to evaluation of the results presented. A perfectly "controlled" experiment on the behavior of human subjects is an ideal rarely if ever achieved. In the experiments presented above, three things were done to maximize control over extraneous factors. First, the cooperation of the subject was sought by explaining the general purpose of the investigation and by stressing the fact that he was more than just the subject. We tried to inspire all subjects to meet the responsibilities imposed by the experiment. An overwhelming majority of the subjects did so.

Second, devices were developed to enable the subject to report his subjective reactions before, during and after each performance. This material will be reported subsequently.

Third, the experiments were designed so that each subject would be studied several times under each drug, the aim being to minimize the effects of inevitable chance factors which might influence any single performance.

Recapitulation of Findings.—The experiments presented above indicated that 14 mg. of amphetamine per 70 kg. of body weight taken two to three hours before running, swimming, or weight throwing improved the performance of the athletes, considered as groups. (Some individuals in each group showed impairment rather than improvement). In the first experiment, 14 of the 15 swimmers (93%) were helped by amphetamine when swimming under rested conditions and 67% were helped when swimming under fatigued conditions. In experiment 6, swimming under rested conditions at maximum or near maximum motivation, 69% were helped. Of the 26 runners tested under rested conditions in experiments 2, 3, and 4, 73% were helped. Eighty-five percent of the weight-throwers tested under rested conditions were helped. The improvement shown by all three groups of athletes was statistically significant. The levels are indicated above.

* #P and #A indicate the number of placebo and amphetamine sessions, respectively. The other symbols are defined in earlier tables. The $\bar{P}$ and $\bar{A}$ times are expressed in minutes and seconds. See text for report on statistical analysis of above data.

In terms of the amount of improvement shown by the three classes of subjects, the weight-throwers were first. As a group they showed an improvement of from 3 to 4%. The 26 runners had a mean improvement of approximately 1.5%. The swimmers showed varying degrees of improvement in the various test situations (from 0.59 to 1.16%). The amount of improvement shown has practical importance as well as statistical significance. The subjects of this study were highly trained athletes. Such individuals may spend months working for an improvement of 1 or 2%.

The 100 mg. per 70 kg. dose of secobarbital produced a significant impairment in the performance of the subjects (15 swimmers in experiment 1) receiving it. The 50 mg./70 kg. dose produced effects which were in general not significant. Two groups of runners showed slight impairment, and one group showed slight improvement of performance. The weight-throwers obtained a slight improvement. One subgroup of subjects in the latter study obtained an improvement in performance under 50 mg. of secobarbital which was statistically significant. (The secobarbital was used primarily to prevent the subject from correctly assuming he had received a "pep pill" whenever he thought he perceived drug-effects. It was also included to permit a study of the relationship between mood change and change in performance. Both amphetamine and secobarbital are thought to have euphoretic power. Data concerning these questions will be presented later.)

Considered as groups, the 15 swimmers of experiment 1 and the 17 runners of experiments 2 and 3 performed poorer (under placebo) during the experimental sessions than during meets with other schools. No such comparison was possible with the 9 marathon runners because they did not run competitive distances for the experiment. Considered as a group, the 13 weight-throwers threw as far in the placebo experimental sessions as in meets. The 16 swimmers of experiment 6, who performed under the special motivation described above, achieved experimental times which were, in general, equal to their meet times.

Generalization Concerning Intercollegiate Competition.—The findings presented above do not prove that athletes performing in intercollegiate meets would be helped by amphetamine. Practical considerations prevented our testing the drug under conditions of official school competition. However, experiments 5 and 6 succeeded in obtaining "all out" efforts from the subjects and thus provided pertinent information which should be stressed. Experiment 6 was designed specifically to stimulate maximum effort and to approximate the psychological atmosphere of a competition with another college. The 16 subjects, considered as a group, swam as fast during the experimental sessions as they had during meets with other schools. Under these circumstances amphetamine produced an improvement in performance which was significant beyond the 0.05 level.

In experiment 5 the 13 weight-throwers achieved experimental performances which were as good as those they achieved in intercollegiate meets. Here, also, amphetamine produced an improvement for the group which had both practical and statistical significance. The average improvement was from 3 to 4%.

Both the subjective data to be reported subsequently and the measured performance data reported above, indicate that amphetamine sulfate, in the 14 mg. per 70 kg. of body weight dose, taken two to three hours before an intercollegiate meet will improve the performance of the majority of runners, swimmers, and weight-throwers.

Summary and Conclusions

Six experiments were carried out on swimmers, runners, and weight-throwers to determine whether amphetamine sulfate in the dose of 14 mg. per 70 kg. of body weight improves the measured performance of such athletes. The experiments employed the double-blind procedure, placebos, and additional comparison medications (50 and 100 mg. per 70 kg. of secobarbital). Eighteen swimmers were studied a total of 453 times, 26 runners gave 205 performances, and 13 weight-throwers gave 123. The medicaments were given orally, and the performances were measured from two to three hours after the subjects had taken either amphetamine or placebo. The experimental conditions maintained and the methods used to evaluate performance were described in detail. The results of each experiment were evaluated statistically. Data obtained in an exploratory investigation using a smaller dose level of amphetamine (7 mg. per 70 kg.) were also reported.

In all three classes of athletes, the majority of subjects performed better under influence of amphetamine (14 mg. per 70 kg.) than placebo. The improvement was statistically significant for all three classes of athletes. Eighty-five per cent of the weight-throwers, 73% of the runners, and from 67 to 93% of the swimmers performed better under influence of amphetamine than placebo. The weight-throwers obtained the greatest amount of improvement from amphetamine (from 3% to 4%); the runners obtained an improvement of approximately 1.5%; the swimmers showed varying degrees of improvement in the various test situations (from 0.59 to 1.16%). The relationship of the data obtained to the use of amphetamine in intercollegiate competition was discussed.

This study has shown that the performance of highly trained athletes, of the classes studied, can be significantly improved in the majority of cases (about 75%) by the administration of amphetamine.

This work was supported primarily by a grant from the American Medical Association. In addition it was supported in part by the Medical Research and Development Board of the United States Army and in part by the United States Public Health Service.

The authors wish to express their appreciation to Prof. William Cochran and to Prof. Frederick Mosteller for advice concerning matters of experimental design and statistical analysis; to Wayne Finegar, Sandra Levenson, Michael Breen, Paul Royte, Clay Black, and Shirley Howard, who assisted at various stages of the investigation; and to the coaches and athletes whose cooperation and aid made the study possible.

INCREASING IMPORTANCE OF LEUKEMIA.—A disease which has doubled its incidence in 9 years is worthy of attention, even if it presents only a comparatively small threat to public health.

In Western Germany the number of deaths registered as due to leukaemia, including aleukaemia leukaemia, doubled between 1948 and 1956. The increase was greater in women than in men, so that the previously marked difference in incidence between the sexes has been narrowed. The greatest increase has taken place in old people; certain other age groups show little or no increase. Part of the increase may be due to improvement in medical care, but it remains open to what extent this factor is responsible.—G. Neumann, The Mortality from Leukaemia in Western Germany from 1948 to 1956, *German Medical Monthly,* March, 1959.

EFFECT OF AMPHETAMINE SULFATE ON ATHLETIC PERFORMANCE

Peter V. Karpovich, M.D., Springfield, Mass.

Recently there has been a great deal of agitation regarding the use of amphetamines in athletics. This agitation has been based mainly on rumors or secondhand information regarding one or two athletes who reportedly have admitted the use of amphetamine (Benzedrine) sulfate. It is, however, not known how these athletes would have performed with and without this drug under conditions of a controlled experiment.

While it is well known that amphetamines can cause euphoria and various degrees of insomnia which prolong wakefulness which might be used for activity, no reliable evidence exists that amphetamines are effective in increasing either endurance or speed in athletic activities. For this reason, the present study was undertaken. This study was so designed that it would be possible to detect the effect of the drug on endurance, recuperative ability, and speed of athletic performance under two conditions: "laboratory" conditions and under emotional stress during actual athletic competition.

Methods

Activities.—The following activities were included: (1) running to exhaustion on an electrically driven treadmill at 7.2 mph and 5-degree inclination twice in succession with a 10-minute rest in between the runs, (2) swimming 100 yd. as fast as possible twice in succession with a 10-minute rest in between, (3) swimming 220 and 440 yd. once on each testing day, (4) running 220 yd. on an outdoor track for time trials, and (5) running various distances (from 100 yd. to 2 miles) during competition. Altogether 532 tests were used for statistical analysis.

All "laboratory" experiments consisted of six tests done on six different days, three times with the drug and three times with a placebo. Experiments during actual contests were planned so that each subject would run from four to eight times, one-half of the runs with amphetamine and one-half without. However, since it was not always possible to know ahead of time what subject would take part in the contest, the number of tests and the order of administration of the drug and placebo varied.

Medication.—From the standpoint of medication, this study may be divided into two parts. In 1958 all but four subjects were given a capsule of 10 mg. of amphetamine sulfate one hour before the test. These four subjects received 20 mg. 30 minutes before the test. The drug and the placebo were administered from six coded bottles and given to subjects in rotating order. Neither I nor my assistants knew the code, which was kept in the A. M. A. headquarters on my request.

In 1959, although the drug and the placebo were administered from coded bottles, I, but not my assistants, knew the code. This was done in order to expedite the detection of individuals who were affected either beneficially or deleteriously by the drug so that they could be subjected to additional tests. In 1959 all subjects received 20 mg. of amphetamine or placebo 30 minutes before the test. In both series, the placebo was made of calcium lactate.

Subjects.—All subjects were male college students. Most swimmers and all trackmen were varsity men. All the treadmill runners, some of whom were also varsity men, received preliminary training in running on the treadmill. Twenty-five men were used on the treadmill, 18 in swimming, and 11 in track time trials during competition. Altogether, 54 subjects were used. All subjects had a medical examination. Blood pressure and pulse rate were taken on several occasions one-half hour and one hour after medication. Since no particular variations were observed, this procedure was discontinued.

Amphetamine total minus placebo total	—0.38								—5.27			—11.85			4.1		

* Subjects in each group, except "Treadmill (10 Men)," received at least 6 tests. In this group only 4 tests were given. Analysis of variance of performance time and also of variance in time differences between first and second "runs" in swimming and treadmill running showed no statistically significant differences between effects of amphetamine and placebo.

† Varsity meets, 100, 220, and 440 yd.; ½, 1, and 2 miles. Time of running with the placebo was taken as 100%.

From the Department of Physiology, Springfield College.

Results

Treadmill Runs.—Tests with 10 mg. of amphetamine given to 11 subjects one hour before the run showed no evidence of either a beneficial or deleterious effect of the drug on the endurance and recuperation from fatigue. From the table it may be seen that the average times for the first runs were 391.06 seconds with the drug and 398.24 seconds with the placebo. The duration of the second run was 281.63 seconds with the drug and 279.72 with the placebo. The average total times were 672.69 seconds and 677.96 seconds respectively. Analysis of variance of times showed that the differences between the figures in each pair were not statistically significant.

Tests with 20 mg. of amphetamine given to 10 subjects one-half hour before the run also gave no statistically significant difference (see table).

Tests with Amphetamine on a Special Group: Four men, highly interested in the experiment and therefore highly motivated to do their utmost, were each tested seven times. Most of the subjects felt a sense of euphoria after taking the capsule containing 20 mg. of amphetamine, the effect being noticeable about 30 minutes after taking the capsule. They also thought that they could run longer when they felt this effect, but they did not.

It may be observed from figure 1 that the best times for the first runs were obtained by all subjects during the last session regardless of the chemical taken: two of the subjects had taken amphetamine and the other two a placebo. The psychological effect of the knowledge that it was the last test was obvious. Although the average results obtained for the entire group are the same as those obtained in other treadmill experiments, there was a definitely different reaction on the part of one of the subjects. Subject 3 (figure 1) exhibited a deleterious effect of amphetamine. His drug times were shorter than the placebo times. The average drug time was only 284 seconds, whereas the placebo time was 357 seconds. Unfortunately this subject was not available for further experimentation. Subject 2 showed a puzzling behavior occasionally observed in experiments involving endurance testing and not related to the chemicals consumed. His first and last runs were the best. Since the improvement in the last run had psychological reason, a similar interpretation may be suggested regarding the first run.

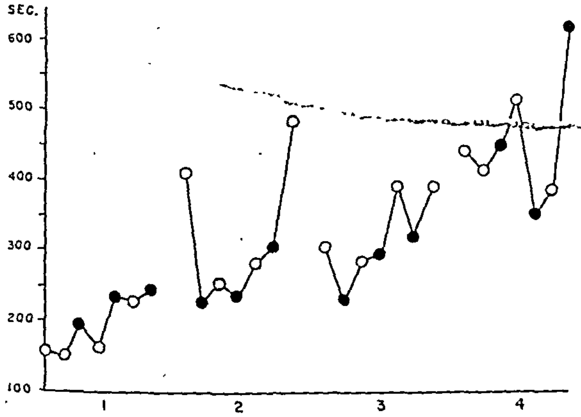

Fig. 1.—Effect of amphetamine (20 mg. taken one-half hour before test) on treadmill running time. Speed, 7.2 mph; angle of inclination, 5 degrees. (Solid dot, amphetamine; open dot, placebo.)

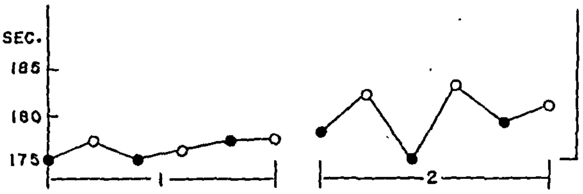

Fig. 2.—Effect of amphetamine (20 mg. taken one-half hour before the test) on speed of swimming 220 yd. Part 1 was obtained during the swimming season and part 2 after season. (Solid dot, amphetamine; open dot, placebo.)

Swimming.—Tests were made with 10 mg. of amphetamine given to 11 subjects one hour before swimming 100 yd. The average time for the first swim was 62.34 seconds with the drug and 62.33 with the placebo. For the second swim the times were 62.81 and 63.20 seconds respectively (see table). Analysis of variance showed that these differences were not statistically significant. Thus no beneficial or deleterious effect of amphetamine was observed on either the speed of swimming or recuperation from fatigue.

Tests were also made with 20 mg. of amphetamine given 30 minutes before swimming. Nine subjects swam 440 yd. The average drug time was 311.6 seconds and the placebo time 311.0. Two groups of subjects swam 220 yd. In one group, consisting of 16 men, the average drug time was 168.62 seconds and placebo time was 169.64 seconds. In the second group, consisting of 11 men, the times were 151.2 and 151.6 seconds respectively. Statistical analysis showed that the difference between each pair of figures was not statistically significant.

Inspection of the time graphs made for each subject showed that there were three subjects whose speed was increased by the amphetamine. Figure 2 shows a time graph prepared for one of these subjects. This graph consists of two parts. Part one was obtained when the subject was at the peak of condition. During this period, one can see a trend. The two fastest times were made with the drug during part two, after the swimming season was over, and the subject's speed fluctuated eight seconds instead of two seconds as in part one. The effect of amphetamine was observed each time he took the drug. The second man, a much faster man whose time varied from 143 seconds to 146 seconds, swam faster each time he took amphetamine. Without the drug, his average time was 146 seconds; with the drug it was 143.3 seconds. One subject swam 440 yd. faster each time with amphetamine than with placebo. This average drug time was 301.6 seconds, and placebo time was 303.3 seconds. His swimming time for 220 yd., however, was not affected.

Track Running with Amphetamine Taken One Hour Before Test.—Nine varsity men were tested six times, after taking 10 mg. of amphetamine, each in time trials for 220-yd. runs. The average running time after taking amphetamine was 25.13 seconds and after taking the placebo 25.15. Analysis of variance showed that there was no statistically significant difference between the times.

Competitive Track Runs.—Twelve men made 65 runs in seven events: 100 yd., 220 yd., 220 yd. with low hurdles, 440 yd., ½ mile, 1 mile, and 2 miles. If the time of running after taking the placebo is given a value of 100%, the average time of running after taking the drug is 99.4%. The best time was made 11 times with the drug and only 9 times with the placebo. There were two ties. This observation, however, cannot be accepted as even an indication of a trend.

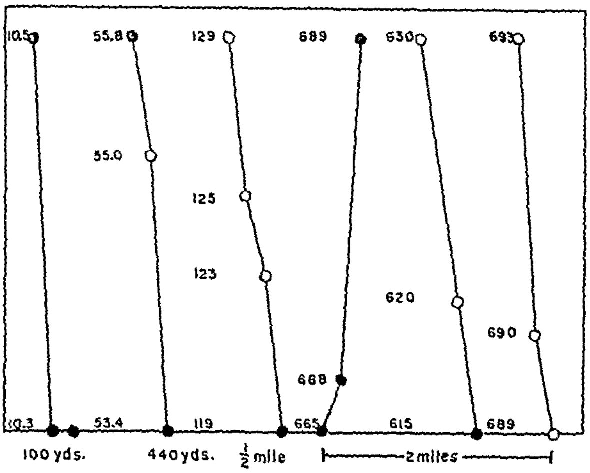

Fig. 3.—Time graphs obtained during intercollegiate track meets. Running time of some subjects improved and that of some deteriorated regardless of the chemical taken. (Solid dot, amphetamine [20 [illegible] one hour before the run]; open [illegible], placebo.)

An inspection of the individual time graphs shows a disturbing fact (fig. 3). Some runners showed a consistent improvement in speed and some a consistent deterioration in performance regardless of the chemical taken.

Looking at the 100-yd. record, one may assume that this man improved under the influence of the amphetamine. The 440-yd. man improved also, even though before his second run he received the placebo. The half-miler kept on improving while getting placebos, and one may suppose that he would have improved during his last run if the placebo instead of amphetamine had been given (as happened with the last two-miler). The first two-miler's performance became steadily worse in spite of or because of amphetamine.

Comparison of weather and track conditions with the records failed to show any relation. If by chance tests were made only on subjects 1, 3, or 5, conclusions could be drawn that amphetamine increases the speed of running. The graphs 4 and 6 in figure 3 will make one wonder. It is quite possible that these steady changes in performance are not related to the effect of the drug at all.

Subjective Reports

Subjects were asked to report any unusual sensation, comfortable or otherwise, and whether they slept well or not. When 10 mg. of amphetamine was given, the placebo was blamed or praised as often as the drug. When 20 mg. was given, the subjects were 75% correct in guessing when they had been given the "pep pills." Some complained of difficulty sleeping. The latter was remedied equally well by a sedative or another capsule of placebo. The four subjects in the special treadmill group usually guessed correctly when amphetamine was administered. In this group there was a man from India who had never taken any drugs in his life and was at first reluctant to join in the experiment. He could always guess correctly whether it was a drug or a placebo that had been taken. However, this did not affect his running time.

Comment

During the experiment subjects did not know what drug was being investigated. Their guesses ranged from amphetamine to tranquilizers. The medication schedule was adhered to strictly except in one instance when a man, after taking the drug, ran half an hour later than scheduled. When, on one occasion, trackmen did exceptionally well, they begged for more of the "miracle pills." Subsequent examination of records revealed that some of these "miracle pills" were placebos.

Examination of individual records of competitive runs shows that for no known reason some athletes steadily improved and some steadily declined in proficiency during the last three meets. If, by chance, only certain men had been used in this study, results could have been either definitely in favor of or definitely against amphetamine.

Four subjects in the special treadmill group gave their best performance during the last test. It was fortunate that two of them had received amphetamine and two the placebo. If they all had received the same chemical, interpretation of the results would have been more difficult.

There are other stumbling block may be
encountered. On one occasion, a mproved
his endurance 88% (from 402 se
onds) after taking 10 ıg. of ar
ever, a few days other

taking 10 mg. of placebo, improved his endurance more than 132% (from 860 seconds to 2,000 seconds). He ran on three more occasions, twice with the drug and once with the placebo, but his time never surpassed 958 seconds. This particular man was a good distance runner and very cooperative. He could not offer any acceptable explanation of his phenomenal run. Such unusually long running times immediately arouse a suspicion that these two men were not always running to the limit of their ability, a suspicion easily aroused when tests depend on maximum voluntary performance. However, there was no other tangible evidence on which to suspect these two subjects of shirking their pledges, and they were retained in the experiment.

Observations similar to this have been made by me during other experiments involving endurance. No suitable explanation has ever been found.

The results obtained during track contests were different from those obtained on the same men during the 220-yd. trials. Whereas during the trials no effect on performance was discovered, the data obtained during athletic competitions could be interpreted in a manner fitting the fancy of the interpreter. All reports regarding the ergogenic action of chemicals obtained from studies of single individuals or small groups should be regarded with extreme caution. It is also advisable to plot performance graphs for each subject, so that any unusual reaction can be discovered immediately and followed up with additional tests.

Summary and Conclusions

In an investigation of the effect of amphetamine sulfate on the athletic performance of 54 male college students, the drug was given in doses of 10 and 20 mg., either one hour or one-half hour before the test. Activities used were as follows: running to exhaustion on a treadmill twice in succession with a 10-minute rest in between, running 220-yd. track time trials, running distances from 100 yd. to 2 miles under competitive conditions, swimming 100 yd. twice in succession with a 10-minute rest in between, and swimming 220 and 440 yd. Altogether 532 tests were statistically analyzed. All subjects but four showed neither beneficial nor deleterious effects of 10 or 20 mg. of amphetamine. Three of the four subjects definitely improved in swimming 220 yd., while one improved in swimming 440 yd. One treadmill subject showed a deleterious effect of amphetamine. He ran longer after taking the placebo than after the amphetamine. Thus, three of the subjects were definitely benefited by the amphetamine, and one man was affected deleteriously. All these men received 20 mg. of amphetamine.

I wish to thank Messrs. Derwood Stetson, John Hichwa, Chalasani Rao, and Coach Charles E. Silva and his staff for assistance with the experimental work; Drs. Clifford E. Keeney and Emery Seymour for statistical help; and Miss Clare E. Condron and Mr. Richard McCorkle for assistance in preparation of the manuscript.

This study was aided by a grant from the American Medical Association.

MYXEDEMA.–Myxedema is the commonest form of thyroid disease seen by the physician. . . . Since the use of radio-iodine therapy has become widespread, two types of decreased thyroid function are seen. The first is a transitory state occurring about three to six months after therapy, which we have called hypothyroidism. The patient complains of feeling the cold and of gain in weight, while the diastolic blood pressure has always been found to be elevated in these patients. They do not show the florid features of myxedema and respond well to replacement therapy with moderate doses of thyroid gland extract. The importance of the separation of this group is that the symptoms are temporary and, after six months' therapy, the thyroid apparently recovers. It is probably due to temporary excess destruction of the secreting tissues, or to too prolonged use of antithyroid drugs after radioactive iodine therapy. Unfortunately, typical permanent myxedema may be seen after radio-iodine therapy . . . (most figures vary between 5% and 10%). The recent discovery of triiodothyronine and the acetic acid derivatives has stimulated investigation of their use in myxedema. All these substances have been found to be effective in relieving symptoms, but it is generally agreed that they are not suitable for general use. Triiodothyronine is two to five times more potent than thyroxine. Its action is rapid and may therefore precipitate cardiac complications in the elderly. There is a very definite withdrawal syndrome, seen within 24 hours of ceasing therapy. There is a rapid return of the symptoms and signs of myxedema, which may be even more severe than before treatment. This, of course, is explained by the rapid dissociation of triiodothyronine from the globulin in the serum to the intracellular department. Its main use is in myxedema coma, in which it may be lifesaving.–W. E. King, Medical Aspects of Thyroid Disease, *The Medical Journal of Australia,* Dec. 20, 1958.

USE OF AMPHETAMINES IN ATHLETICS

GUEST EDITORIAL

Allan J. Ryan, M.D., Meriden, Conn.[*]

IN JUNE, 1957, a resolution presented to the House of Delegates of the American Medical Association condemned what was alleged to be a widespread use of amphetamine substances by coaches, trainers, and athletes to improve athletic performance. As a result, the Board of Trustees appointed a special committee to investigate these charges. The *ad hoc* Committee on Amphetamines and Athletics conducted a survey of opinions and practices among those connected with the direction and training of athletes. This was done with the cooperation of the National Collegiate Athletic Association, the National Association of Intercollegiate Athletic Associations, and the National Federation of High School Athletic Associations. After many contacts with physicians and other persons connected with amateur and professional sports, the Committee reported to the Board of Trustees that the observed use of these drugs is apparently very small.

A review of the available literature relating to the pharmacology and uses of the amphetamines failed to reveal any well-substantiated evidence that any improvement in athletic performance could be expected as the result of their administration. Dr. Henry K. Beecher, a member of the Committee, therefore volunteered to undertake a study at Harvard University in order to help answer this question. In the meantime it was discovered that Dr. Peter V. Karpovich had already planned a similar investigation at Springfield College in Massachusetts. The Board of Trustees agreed to provide financial support to the Harvard project and assistance to the Springfield investigation. Dr. Karpovich agreed to consult with the Committee regarding his plans and his findings.

The results of these two investigations, which were conducted independently and according to quite different plans, are published in this issue of THE JOURNAL. The Harvard study clearly shows that, when amphetamine is given in a large enough dose (14-21 mg. per 70 kilograms of body weight) and from two to three hours before the test, improvement in speed performance of runners and swimmers, and distance achieved by weight throwers, occurs in about 75% of trained athletes. The Springfield study, using smaller doses with a much shorter time interval (one-half to one hour) showed improvement in performance in only three instances.

Since the use of any drug to improve athletic performance has already been made grounds for disqualification by the International Amateur Athletic Federation, the Amateur Athletic Union, and the United States Olympic Association as being contrary to the highest ideals of sportsmanship, and since the use of amphetamines even in moderately small doses is known in many instances to result in habituation and harmful effects, the Committee has recommended that the use of amphetamines for this purpose be condemned. Because these drugs can be obtained legally only on prescription, a serious obligation devolves on physicians to help prevent such usage by prescribing them only for well-recognized medical indications. It is acknowledged there is an illegal traffic in the amphetamines in the United States and that problems of its control still remain to be solved.

MEDICAL LICENSURE

In the 57th annual report on medical licensure prepared by the Council on Medical Education and Hospitals, which appears in this issue, data are presented concerning the medical examination and the licensure of physicians in the United States and its territories and outlying possessions for 1958. The report also summarizes trends in licensure over many years and presents current regulations pertaining to medical licensure. A section is included pertaining to boards of examiners in the basic sciences and the National Board of Medical Examiners.

---

[*] Chairman, A. M. A. *ad hoc* Committee on Amphetamines and Athletics.

The report calls attention to the nine workshops conducted over a three-year period by the Federation of State Medical Boards of the United States. At these workshops major areas of concern the evaluation of fitness of a state board of medical examiners were subjected to a critical analysis. Relation of concern by a state board to the status of medical education as it exists today in respect to both the medical school and the advanced postgraduate levels of education and training activity was a major consideration.

In 1958, a total of 15,240 licenses to practice medicine were issued by 55 boards authorized by law to grant licenses to practice the art and science of medicine. The 15,240 licenses issued last year represented 7,315 granted after a successful written examination, and 7,925 granted by reciprocity and endorsement of state licenses or the certificate of the National Board of Medical Examiners.

Additions to the medical profession are reflected in a number of tables included in this study. There were, 7,809 physicians who secured their first license to practice medicine and surgery during the calendar year 1958. In the same year, approximately 3,700 deaths of physicians were reported to the offices of the American Medical Association. Thus, the physician population in the United States and its territories and possessions was increased by 4,109.

Failures by graduates of approved medical schools in the United States amounted to 4.3% and by graduates of approved medical schools in Canada 8.3%. The percentage of failures in three other groups—graduates of foreign faculties of medicine, unapproved medical schools, and schools of osteopathy—were 40.9, 76, and 22.2 respectively.

Provision is made by 38 boards for the issuance of temporary and educational permits, limited and temporary licenses, or other certificates of limited registration. The terms for the issuance of these certificates vary and may apply to hospital training, to those ineligible for licensure who seek further educational training, for practice in emergency areas, or for regular practice until the next regular session of the licensing board when permanent licensure is granted. The study further outlines the licensure requirements for interns and residents in hospitals, the states which require an internship for licensure, the preprofessional and professional educational requirements of each licensing board, the schedule of written examination dates and reciprocity meetings, medical license fees, licensure on government credentials, and annual registration requirements.

The Educational Council for Foreign Medical Graduates is referred to briefly in this report and attention is called to the analysis of this evaluation service for foreign medical graduates by Dr. Dean F. Smiley, executive director, which appears elsewhere in this issue.

The Council's study reveals that graduates of foreign medical schools were examined for medical licensure by 43 boards in 1958. Graduates of 231 medical schools and 4 licensing corporations were examined, representing medical schools in the Philippines, New Zealand, 13 South and Central American countries, 26 countries in Europe, and 15 countries in Asia. More than 75 graduates each from the universities of Havana, Munich, Athens, Rome, Mexico, and Geneva were tested in 1958, and more than 20 graduates from 33 other schools were examined. The number who were successful in these tests was 1,518. Failures numbered 1,049, or 40.9% of those examined. Since 1944, there has been a noticeable increase in the number of foreign-trained physicians seeking licensure in the United States. In 1958, the increase over the previous year was 268. During 1958 there were 1,166 foreign-trained physicians licensed who represent additions to the medical profession having secured their first license during the year. Of this group, 1,129 were licensed by written examination and 37 by endorsement of credentials. In an eight-year period, it was shown that 6,483 foreign-trained physicians were added to the physician population of the United States.

That portion of the report pertaining to the results of examinations given by the 22 boards of examiners in the basic sciences reveals that certificates were issued to 6,269 candidates in 1958. Of these, 3,592 were granted after written examination and 2,677 by reciprocity, endorsement, exemption, or waiver. The failure percentage for those reporting this information was 21.9. The basic science laws do not specify that a candidate reveal his school of practice. No attempt has been made in this study to differentiate between the schools and the healing art represented by the candidates examined or certified.

The last series of tabulations refers to the examinations given by the National Board of Medical Examiners. The certificate of the National Board is accepted as a suitable qualification for the practice of medicine by 46 licensing authorities in the states, the District of Columbia, and the territories of the United States. There were 2,011 physicians who were certified as diplomates last year. The largest number of candidates presenting the same type of credential for medical licensure by endorsement last year were 3,215 diplomates certified by the National Board who were licensed in 43 states, the District of Columbia, Hawaii, and Puerto Rico.

This informative study compiled annually by the Council is made available through the cooperation of the various examining and licensing boards; for their cooperation, the Council and THE JOURNAL wish to express appreciation.

ANESTHETIC DANGERS IN HEREDITARY DISEASES

The article in this issue of THE JOURNAL (page 529) by Kritchman, Schwartz, and Papper has drawn attention to the dangers inherent in administering anesthetics to children with familial dysautonomia. Although this condition is relatively uncommon, affected children may require surgery for a variety of reasons. The most outstanding clinical manifestations of familial dysautonomia are related to abnormality of function of the autonomic nervous system. Kritchman and associates described a series of eight patients who received general anesthesia for 27 surgical procedures. Severe hypotension occurred as a complication of anesthesia six times, and cardiac arrest occurred in two patients, requiring open-chest cardiac massage and resuscitation. Bronchopneumonia and atelectasis were frequent postoperative complications. The instances of circulatory collapse were associated with the use of thiopental sodium or tribromoethanol (Avertin). These investigators recommended the use of local anesthesia or a volatile anesthetic agent if surgery is required in patients with famliial dysautonomia.

An increased anesthetic risk also exists in patients with the hepatic type of porphyria. In these patients the condition often remains undiagnosed for many years, and they are often dismissed as "neurotic." Episodes of abdominal pain that may simulate surgical emergencies are common. Dean [1] described 12 patients in 11 family groups in whom the disease was discovered because of reaction to intravenous barbiturate anesthesia. The diagnosis of porphyria was unsuspected prior to operation. Acute episodes of porphyria with paralysis were induced by the anesthetic, and three of the patients died. Porphyria of the hepatic type is conditioned by an autosomal dominant gene, and we therefore expect one parent and half of the sibs and children of any patient with this type of porphyria to possess the gene and to present either clinical or subclinical evidence of the disease. Dean traced the relatives of his 12 original patients and located 216 relatives with evidence of porphyria, and a number of these had experienced acute exacerbations after barbiturate medication.

It seems at least possible that an increased anesthetic risk may also exist in patients with sicklemia, the carrier or heterozygous state of the gene for sickle cell anemia. Cooley and associates [2] described as a clinical triad the association of massive splenic infarction, sicklemia, and high altitude flying. It is well known that the tendency of erythrocytes containing hemoglobin S to assume the characteristic sickle shape is enhanced by lowering of the oxygen tension. Presumably, partial anoxia induces changes in the erythrocytes which predispose to thrombosis and infarction. Accidental hypoxia is at least a risk during general anesthesia, and patients with sicklemia may develop thromboses if the oxygen tension is reduced sufficiently for a sufficiently long period. As approximately 7% of American Negroes have asymptomatic sicklemia, the proportion of surgical patients exposed to this risk is significant. Doenges and associates [3] have suggested that the much smaller group of persons who have both hemoglobin S and hemoglobin C may be more susceptible to the effects of hypoxia than those with hemoglobin S alone.

It is also worthy of note that patients with gout are likely to have acute exacerbations after any operative procedure. Acute attacks of gout may also be precipitated by trauma and ingestion of alcohol and certain drugs including ACTH; it has been suggested that stress producing a syndrome of increased adrenal cortical activity may be the mechanism common to these precipitating factors.[4] It has also been suggested that patients with gargoylism react poorly to anesthetics.

Observations such as these suggest that we should approach problems of anesthesia and chemotherapy in patients with hereditary diseases with some caution. Mutant genes must produce their effects by some alteration of biochemical function. Specific enzyme deficiencies have been found to be associated with specific genotypes in a number of conditions,[5] but the postulated biochemical change in many other hereditary conditions still eludes definition. The person with genetic differences may be inherently different from the majority of the population in his reaction to some type of environmental stimulation. An unusual reaction, or idiosyncrasy, to an anesthetic or other drug may be an expression of a genetically determined inherent difference in the patient so reacting. Such reactions will become predictable and preventable only when sufficient observations such as those mentioned above have accumulated and when the predisposing genetic diseases are regularly identified in specific patients and their families.

INTRODUCTION

Statistical compilations regarding medical licensure are presented annually in the State Board Number of THE JOURNAL. Data are included pertaining to (a) medical examining and licensing boards of the United States, the District of Columbia, and the territories and possessions of the United States, (b) the boards of examiners in the basic sciences, and (c) the National Board of Medical Examiners. The report also contains a résumé of the reevaluation of the medical licensing examination sponsored by the Federation of State Medical Boards of the United States and a summary account of the activities of the Educational Council for Foreign Medical Graduates.

The computations presented are based on official records received throughout the year from all medical examining and licensing agencies of all states, Alaska, the Canal Zone, Guam, Hawaii, Puerto Rico, and the Virgin Islands. Alaska is recognized as a state in these compilations. The figures for Connecticut also include data reported by the homeopathic medical examining board of that state. The only other homeopathic board in operation, in Louisiana, had no new licentiates last year. Data are also included pertaining to the 22 boards of examiners in the basic sciences and, last, the National Board of Medical Examiners. The Council and THE JOURNAL gratefully acknowledge their appreciation to those who have supplied these data as well as other records furnished throughout the year to the American Medical Association.

A NEW ERA IN LICENSURE

At the 55th Annual Congress on Medical Education and Licensure, the Federation of State Medical Boards completed the formal sessions devoted to the reevaluation of the medical licensing examinations. In nine separate workshops covering a three-year period, the major areas of concern in the evaluation of fitness by a State Board of Examiners were subjected to a critical analysis of the relation of concern by a board to the state of medical education as it exists today both in respect to the medical school and the advanced postgraduate levels of educational and training activity.

Combined with the examination institutes, the programs of the federation in the past three years have been designed to explore, both from within and from without, the attitudes of licensure in respect to the necessities of change, the shifting of population groups, and the redefining of what fitness means in terms of the greater stability of medical education today. State Boards are aware now that the earlier introduction of clinical experience and the earlier assumption of responsibility for patient care mean a much more concentrated concern over the quality of fitness by the medical schools prior to the time a student graduates than was the case some years ago. There is now a greater

---

In the descriptive data, reference is made to the total number of boards for which figures are reported. The figures include the examining and licensing boards in the territories and possessions and also the homeopathic board of Connecticut.

interest in directions and quality in both preprofessional and professional education and a much more definite tendency to be tolerant to experimental programs in education.

There is no opposition in licensure now to the reallocations of time and the pruning procedures needed in the modern medical curriculum. There is, indeed, a growing interest in the federation in the more radical experiments in medical education and a more intelligent interest in what Dean Berry of Harvard College calls "a dynamic and tremendously complex environment."

At the end of the initial series of institutes, one of the most interesting results was the evidence that the primary challenge of reevaluation of the licensing examination is to the examiner and not to the examinee. It is on this evidence that the federation asserts that it is moving into a new era. The number of examiners who attended one or more of the institutes, and the interest they developed in self-improvement, insures that the responsibility of constructing licensing examinations which involve patient problems will increasingly result in better and more practical examinations.

In summing up the experiences of the institutes, the federation recognized that, with frequent changes occurring on Boards of Examiners, there will be a constant need to orient new members to the newer concepts of the realistic purposes of the licensing examination. As a result, there will be an annual examination institute for this purpose. With this objective, there will be opportunity to review, annually, the significant developments of the past year in respect to progress in experimental programs of education and shifts of interest in the total area involved in the education of the physician.

After the completion of the institutes, it was apparent that the decision of the Federation of State Medical Boards to consider that it was moving into a new era was one based upon a much more definite realization that licensure is a vital component of all the interests which are directed toward preserving and improving the quality of medical care in the United States. Thus, the federation accepts the responsibility of being realistic and tolerant in its attitudes as well as the necessity to maintain a constant concern over its policies and procedures.

The federation faces a number of significant problems for future consideration in the field of discipline, the type and construction of examinations best suited to licensure purposes, the problems related to various types of addiction in the licensed groups operating in the health field, and the educational standards involving the increasing number of ancillary groups attached to the periphery of medical practice.

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES

The Educational Council for Foreign Medical Graduates began operation on Oct. 1, 1957. It has held three examinations to date. Sponsoring agencies are the American Hospital Association, the American Medical Association, the Association of American Medical Colleges, and the Federation of State Medical Boards of the United States. The Board of Trustees of the Educational Council includes representatives from each of these organizations and two members representing the public at large. Its stated purpose is to provide information to foreign medical graduates, to translate and evaluate foreign educational credentials, and to test the foreign medical graduate's command of English and his basic knowledge of medicine. Elsewhere in this issue, Dr. Dean F. Smiley, Executive Director, presents an analysis of the three qualifying examinations thus far held and outlines the plans for future examinations.

MEDICAL LICENSURE STATISTICS

The tables referring to medical licensure present figures pertaining to the number of candidates examined, the number licensed, and the number who represent additions to the physician population. Data are also included pertaining to the regulations for medical licensure both of physicians who secured their professional training in the United States and Canada and of physicians educated in other countries. The state boards are discussed first, followed by the basic science boards and the National Board of Medical Examiners.

STATE BOARDS OF MEDICAL EXAMINERS

Licenses Issued

In 1958, 15,240 licenses to practice medicine were issued by 55 boards authorized by law to grant licenses to practice the art and science of medicine. The number licensed by each of these boards by examination or by endorsement of credentials is shown in table 1. Of the 15,240 licenses issued, 7,315 were granted after written examination and 7,925 by reciprocity and endorsement of state licenses or the certificate of the National Board of Medical Examiners.

Physicians certified in a given year after written examination were not in all instances tested in that year. Approximately one-half of the boards require a year of internship as a prerequisite for licensure. The candidate for licensure in some states is permitted to write the examination before or while serving an internship and, if he is successful, the license is issued on completion of the internship and dated the year in which issued. Licenses are withheld in some states for other technicalities. In general, also, the licenses of physicians examined in December are dated and issued in the early part of the next year. Table 1, therefore, includes some data on physicians who were examined in 1957 and a few who were examined in previous years. Thus, the figures presented in this table will not correspond with succeeding tables that deal entirely with physicians examined for licensure within the year 1958. In tables 12, 13, and 14 can be noted the number of physicians who secured their first license in 1958 and who thus represent additions to the medical profession in the United States and its territories and possessions.

Of the 15,136 licenses to practice medicine and surgery issued in 1958, both by examination and by reciprocity and endorsement of credentials, the greatest number (2,205) were issued in California. New York licensed 1,584, while more than 500 each were registered in Illinois, Ohio, Pennsylvania, and Texas. Alaska, Delaware, Idaho, Montana, Nevada, North Dakota, South Dakota, Vermont, and Wyoming issued less than 50 each. Among the territories and possessions, Puerto Rico licensed 107, Hawaii 44, the Canal Zone 6, and Guam and the Virgin Islands 2 each. There was an increase of 104 in the total number of licenses issued in 1958 as compared with the previous year. Candidates licensed by reciprocity and endorsement increased by 439 the number licensed in 1957, while those licensed after written examination showed a decrease of 289.

Totals	7,315	7,925	15,240

Tables of the physicians licensed for 23 previous years and for 1958, by both examination and reciprocity or endorsement, are included in table 2. Beginning in 1936, there was a marked increase in the number of physicians licensed representing principally the licensure of foreign-trained physicians. The increases in 1946 and succeeding years were the result of the increase in the production of physicians by the medical schools of the United States and Canada, the licensure of foreign-trained physicians, and in the reciprocity and endorsement group the movement of physicians to other locations for practice. In the 24 years from 1935 to 1958, 282,486 medical licenses have been issued, 153,577 after written examination and 128,909 by endorsement of credentials.

Candidates Examined

In table 3 are recorded data referring to applicants for medical licensure by 53 licensing boards. For each board is given the number who passed and failed, the medical school of graduation, the percentage of failures for each school, as well as each licensing board, and the number of states in which graduates of a given school were examined. Approved medical schools in the United States that are no longer in existence, foreign faculties of medicine, unapproved medical schools, and schools of osteopathy are not listed by name, but the numbers examined in these three categories are included after those for existing medical schools in the United States and Canada.

Throughout the last calendar year 8,633 candidates were examined, of whom 7,268 passed and 1,365 failed. The candidates represented graduates of 78 existing approved medical schools of the United States, 11 approved medical schools of Canada, one approved medical school in the United States no longer in operation, 235 faculties of medicine or licensing corporations of other countries, 5 unapproved medical schools in the United States

Table 2.—*Licenses Issued, 1935-1958*

that are no longer in operation, and 8 schools of osteopaths. Osteopaths who were granted the legal right to practice medicine, surgery, or both, by the medical examining boards, are included in these statistics. Osteopaths in other states who were granted the privilege of special practice by other than medical examining boards are excluded from these compilations.

Examination and reciprocity meetings are scheduled at frequent intervals by licensing boards in most of the states to facilitate licensure and to enable physicians to commence practice without undue delay. Later in this study a tabulation is included giving the schedules for all states. The publication of the dates for examinations and reciprocity or endorsement meetings is a regular biweekly feature of THE JOURNAL.

Represented among the 8,633 examinees were 5,692 graduates of approved medical schools in the United States, of whom 4.3% failed; 168 graduates of approved schools in Canada with 8.3% failures; 1 graduate from an approved medical school no longer in operation who passed; 2,567 graduates of faculties located in countries other than the United States and Canada, 40.9% of whom failed; 25 graduates of unapproved medical schools at one time in existence in the United States, with 76.0% failures; and 180 graduates of schools of osteopathy with 22.2% failures.

As in table 1, the 8,633 examinees do not represent an equal number of persons, since a candidate tested in more than one state in a calendar year is counted in each state. If a candidate failed more than once in a given state within the year, however, he is counted in that state as an individual or a single failure. Figures that show the number of individual licentiates added to the medical profession in 1958 are given in tables 11, 12, and 13.

The University of Tennessee, a state university, had the greatest number of graduates for any one school examined for medical licensure in 1958. There were 191 graduates examined, of whom 104 were tested in Tennessee and 87 in nine other states. The greatest number examined from a private school was 167 representing Jefferson Medical College; they were tested in 12 states, with 130 being tested in Tennessee. Eleven public and eight private medical schools each had more than 100 of their graduates examined for medical licensure in 1958, as follows:

Public Medical Schools	No. of Examinees	No. of States in Which Examinations Were Taken
Medical College of Georgia	109	2
University of Illinois	142	14
Indiana University	164	8
State University of Iowa	109	8
Louisiana State University	100	3
University of Michigan	181	5
University of Minnesota	120	8
Ohio State University	157	6
University of Tennessee	191	10
University of Texas	148	2
Medical College of Virginia	115	10

Private Medical Schools	No. of Examinees	No. of States in Which Examinations Were Taken
Northwestern University	104	20
University of Louisville	106	2
Tulane University	147	8
St. Louis University	129	8
Washington University	106	7
Hahnemann, Philadelphia	108	14
Jefferson Medical College	167	12
Temple University	130	18

The Albany Medical College, with five examinees, had the fewest applicants for medical licensure by written examination before state boards. Five other medical schools were represented with fewer than 10 graduates—Yale, Chicago Medical, Boston, Tufts, and Syracuse. The majority of the graduates of these schools are licensed by endorsement of the certificate of the National Board of Medical Examiners.

There were 168 graduates of 11 of the approved medical schools in Canada tested for medical licensure in 1958 in 27 states and Hawaii. The figures are given for each licensing board by school in table 3 and the numbers examined in each state in table 4. Of the 168 candidates examined, 154 passed and 14, or 8.3%, failed. The University of British Columbia, an approved medical school, had no graduates appearing before state boards. The University of Saskatchewan graduated its first class of students in 1957, but none appeared for licensure in the United States in that year. In 1958, however, there were two examined and both passed.

One graduate of Rush Medical College, an approved school no longer in operation, was examined in Georgia, and passed. All other graduates of approved medical schools represented in table 3 were from existing institutions. Graduates of five unapproved medical schools were examined in five states. The schools represented in this group are no longer in operation in the United States. There were 25 examinees in this category, of whom 6 passed and 19, 76%, failed. Of 180 graduates of eight osteopathic schools examined in 11 states, 140 passed and 40, 22.2%, failed. Graduates of 235 foreign faculties of medicine were examined by 42 states. There were 2,567 such graduates, with 1,518 successful examinations, and 1,049, or 40.9%, failures.

Totals for the six categories are given in table 5. It will be noted that 4.3% of the graduates of existing approved medical schools in the United States and 8.3% of the graduates of approved Canadian schools failed. The greatest number of failures fell within three groups: foreign faculties of medicine, unapproved medical schools, and schools of osteopathy. Those in these three groups registered by medical boards are separately discussed in later tables.

Consolidated Results of Examinations

The combined results of two groups of examinations, the state medical board examinations and part 3 of the examinations of the National Board of

Medical Examiners, are given in table 6. This table represents a comprehensive analysis of the performance of physicians from individual schools. It will be noted that in some instances schools having failures before state licensing boards had few, if any, failures before the National Board.

In 1958 there were 5,692 graduates of approved medical schools in the United States examined by state boards and of whom 4.3% (243) failed. In the same calendar year 1,951 graduates of these schools were tested in the final examination of the National Board and 12 failed. In both groups, a total of 7,643 were examined, of whom 7,388 passed and 255, or 3.3%, failed.

Of the graduates of Canadian medical schools, 8.3% failed state board examinations while there were no failures among the 63 graduates who were tested by the National Board. Only 9 graduates of foreign medical schools were examined by the National Board, and 2,567 were examined by state boards. One graduate of an approved medical school no longer in existence was examined by a state board, and the National Board also had one such graduate who was certified. There were none examined by the National Board in the approved medical school or osteopathic categories. There is no comparison to be made in the three groups last mentioned.

TABLE 4.—*Graduates of Medical Schools in Canada Examined for Licensure in the United States, 1958*

	Examined	Passed	Failed
Arizona	1	0	1
California	38	37	1
Connecticut	6	5	1
Florida	9	7	2
Hawaii	1	1	0
Illinois	3	3	0
Indiana	4	4	0
Louisiana	2	2	0
Maine	6	4	2
Maryland	5	5	0
Massachusetts	2	2	0
Michigan	8	8	0
Minnesota	22	22	0
Mississippi	2	2	0
Missouri	2	2	0
Nevada	2	2	0
New Hampshire	4	4	0
New York	8	6	2
North Carolina	5	4	1
North Dakota	4	3	1
Ohio	7	7	0
Oregon	1	1	0
Pennsylvania	14	13	1
Rhode Island	1	1	0
Texas	3	3	0
Virginia	3	2	1
Washington	1	0	1
Wisconsin	4	4	0
Totals	168	154	14

The total of all candidates examined by state boards was 8,633, of whom 7,268 passed and 1,365, 15.8%, failed. For both groups, state boards and the National Board, there were a total of 10,656 examined, with 9,279 successful candidates, and 1,377 failures, or 12.9%. Including the National Board figures reduces the over-all percentage of failures by about 3%.

Failures in Medical Licensure Examinations

Licensure failures in 1958 before state medical licensing boards are further analyzed in table 7. In this tabulation is given the number examined in each state, the number who passed and failed, and the percentage of failures.

The following 12 approved schools in the United States had no failures among their graduates in medical licensing examinations last year:

	Number of Graduates Examined	No. of States in which Examinations Were Taken
Stanford University	40	3
Chicago Medical School	6	4
University of Chicago	39	18
Boston University	8	4
Wayne State University	77	2
University of Mississippi	45	2
University of Missouri	35	2
University of Nebraska	84	7
Albany Medical College	5	2
University of Oregon	43	13
University of Pittsburgh	99	9
University of Utah	59	17

It will be noted, referring to table 3, that those states with high percentages of failures examine a considerable number of foreign-trained physicians. The one exception is Florida. This state has no provisions for medical licensure by reciprocal or endorsement registration, and physicians planning semiretirement in a more ideal climate seek licensure in this state. Many of these physicians graduated from medical schools in the early years of the century and experience difficulty in writing examinations.

In general, state licensing boards require the applicant to receive an over-all average of 75%, and at least 60% in any one subject in the written examination in order to qualify for registration. In case of failure in not more than two subjects, in some states the applicant is permitted a second examination within 12 months. A few states consider such persons as conditioned in the subjects in which they fail. Conditioned candidates are not counted as failures in these statistics. When their grades are raised after a successful examination, they are recorded among those who passed.

TABLE 5.—*Source of Candidates Examined for Licensure in the United States, 1958*

Medical Schools	No. of Schools	No. Examined	No. Passed	No. Failed	% Failed
Approved schools in United States	78	5,692	5,449	243	4.3
Approved in Canada	11	168	154	14	8.3
Extinct	1	1	1	0	0.0
Foreign	235	2,567	1,518	1,049	40.9
Unapproved schools	5	25	6	19	76.0
Schools of osteopathy	8	180	140	40	22.2
Totals		8,633	7,268	1,365	15.8

Of the 15,240 persons obtaining licenses in 1958, 258 failed state board tests before obtaining a license. Of these, 124 had one failure, 59 had two failures, 32 had three failures, and 43 had four or

more failures. Twenty-seven physicians failed from 5 to 10 tests before securing licenses. One physician failed 12 tests and another failed 19 tests before achieving success; both of these were foreign-trained individuals. Of all physicians licensed after one or more failures, 258 were foreign-trained and 17 were graduates of medical schools in the United States.

Registration by Reciprocity and Endorsement

A summary of the reciprocity and endorsement policies pertaining to medical licensure is included in table 8. One state, Florida, requires all applicants for medical licensure to pass a written examination. Hawaii and the Virgin Islands do not have reciprocal relations with any state, but Hawaii will endorse physicians certified by the National Board of Medical Examiners. Twenty-two boards require applicants for licensure to obtain a certificate from the board of examiners in the basic sciences of the state. In the section of this report pertaining to basic science boards is included a table outlining the reciprocity, endorsement, exemption, or waiver policies of the basic science boards.

Twenty-nine states, Alaska, and Puerto Rico have reciprocal agreements with specific states. In 19 states, the Canal Zone, and Guam, reciprocity is extended at the discretion of the licensing board. Twenty states, which have reciprocal agreements, also have similar discretionary powers to endorse applicants from nonreciprocating states who present credentials that correspond with those required by their respective states in the year issued. Also in this table is a column indicating the recognition accorded the certificate of the National Board of Medical Examiners.

Additional requirements, including professional practice, citizenship, oral examination, internship, and the fee for a license by reciprocity or endorsement are also recorded. In some states, physicians of Canadian birth are exempted from the citizenship requirement. This is indicated by footnote and is also represented in a later table pertaining to the acceptance of Canadian credentials. Few states will accept graduates of foreign faculties of medicine on a reciprocal basis. Again, details of the requirements of each state for foreign-trained physicians will be found later in this report. Other requirements or exemptions are indicated by footnotes; footnote numbers are referred to in the column headed "Miscellaneous."

This chart is intended to present an over-all picture of the reciprocity and endorsement policies of the licensing boards. It is helpful to physicians who are considering a change in location. The facts recorded, however, are intended to present merely statements of licensure policies. The information here given should be supplemented by direct communication with the licensing boards. A list of the executive officers in charge of medical licensure appears elsewhere in this report.

The procedure in issuing licenses by reciprocity or endorsement varies. Some states consider applications for licensure at any time, while others hold monthly, quarterly, or semiannual meetings. The policy in effect in each state is presented in a later table. In addition, The Journal publishes biweekly the exact dates when applications are considered.

In table 9 are presented data pertaining to the credentials accepted as the basis for licenses granted without written examination in 1958. There were 7,925 so registered on the basis of licenses issued by other states, the certificate of the National Board of Medical Examiners, by special exemption, and by acceptance of service with an agency of the government of the United States. California issued the greatest number of licenses by this method. In this state, 1,656 were registered. New York licensed 1,154. Eight other states licensed more than 200—Connecticut 221, Massachusetts 379, New Jersey 340, Ohio 345, Pennsylvania 241, Texas 237, and Washington 200.

---

Some states have additional requirements for graduates of schools outside the United States and Canada.

+ indicates reciprocal or endorsement relationships have been established; .. indicates no reciprocal or endorsement relationships have been established. (See column—"At the discretion of the board.")

1. D. Declaration of Intention of citizenship. ⊕ in citizenship column indicates full citizenship required; in other columns it implies a requirement.

2. In most cases there is a small additional recording or registration fee.

3. Year of required.

4. Internsh e year's practice.

5. Two years professional practice required.

6. All applicants must be graduates of a medical school approved by the American Medical Association.

7. Just preceding application.

8. Not required if applicant has been in practice more than 5 years.

9. Basic science certificate required either by reciprocity or examination in addition to basic science subjects of National Board.

10. Canadian citizens are required to file first papers.

11. Not applicable to citizens of Canada.

12. Oral examination required when application is based on a license dated five or more years prior to filing application.

13. For reciprocity applicants.

14. Oral examination required.

15. Endorsement of National Board of Medical Examiners, $35.

16. Active practice for a period of not less than three years immediately preceding date of application.

17. Practical clinical examination required.

18. In lieu of its own examination, certificate of National Board may be accepted in whole or in part.

19. Minimum fee.

20. Licentiates of California, Colorado, Indiana, Iowa, Kansas, Massachusetts, New York, and Rhode Island accepted on reciprocal basis at discretion of board.

21. Not required if country in which applicant is licensed will admit to practice citizens of the United States licensed to practice in some state or on proof of requirements similar to those required by California for graduates of foreign medical schools.

22. At discretion of Health Director.

The largest number of candidates presenting the same type of credential were 3,215 diplomates certified by the National Board of Medical Examiners. There were 345 licenses issued in Pennsylvania, 296 in Illinois, 295 in Missouri, 268 in Michigan, 251 in Ohio, and 219 in New York that were presented to other states for reciprocal registration. California, which issued the greatest number of licenses by reciprocity or endorsement (1,656) certified only 173 of its licentiates to other states. Figures in other states were fewer than 200. Forty-one medical officers of one of the federal services received licenses by endorsement of military credentials in six states. Eleven were licensed by six boards on the basis of a license issued in the Canal Zone, Hawaii, or Puerto Rico. None were regis-

the licensing board of the state in which the physician is interested. See page 604.

---

23. Oral examination required if applicant's state requires it.
24. If the applicant passes the examination in the state from which he transfers after the completion of his internship, no practice is required.
25. May require oral examination.
26. Internship accepted at the discretion of the board as the equivalent of two years' practice.
27. Fee, $25.
28. Fee same as applicant's state charges but not less than $50.
29. Graduates of foreign medical schools are accepted at the discretion of the board.
30. Diplomates of National Board not required to have been in practice for three years.
31. Same as required of candidates of state applying for licensure.
32. Not required for licensure by reciprocity.
33. Reciprocity applicants only.
34. Supplemental examination required in certain cases when accepting the examination of a state with whom reciprocal relations have not been established.
35. Applicants issued certificates prior to October, 1953, acceptable.
36. Fee same as applicant's state charges but not less than $75.
37. For matriculants after Oct. 15, 1937.
38. Graduates of foreign schools not accepted.
39. Reciprocity extended at discretion of board to candidates whose qualifications would entitle them to admission to examination and who took examinat on equivalent to that required by this board.
40. Permanent license withheld until completion of citizenship.
41. At the discretion of the board.
42. Graduates of foreign medical schools are not accepted for licensure by reciprocity.
43. Reciprocity extended at discretion of board to states having comparable licensing requirements and which accept Colorado applicants on a substantially equal reciprocal basis.
44. Consecutive years immediately preceding application.
45. Graduates of medical schools in Canada and foreign medical graduates are not accepted for licensure by reciprocity.
46. Must be residents of the Canal Zone or Republic of Panama.

tered presenting a license from Alaska. There were 59 registered by eight boards on the basis of Canadian or foreign credentials, and 8 were licensed by two boards by special exemption.

In table 10 are reported the numbers from individual schools represented by the 7,925 reciprocity licentiates. Every approved medical school in the United States and the University of Puerto Rico had graduates licensed without written examination in 1958. All of the approved Canadian schools were so registered with one exception—the University of Saskatchewan. The 7,925 licentiates included 7,330 graduates of approved schools in the United States and 173 from Canadian medical schools. Licenses without written examination were obtained by 250 foreign-trained physicians; 18 gradu-

ates of approved medical schools no longer in operation were registered, 26 graduates of unapproved medical schools, and 138 graduates of schools of osteopathy. This table reflects the movement of physicians to states other than the one in which they obtained their professional training or in which they first established their practice.

Licentiates Representing Additions to the Medical Profession

The number of licentiates of 1958 who received their first license to practice medicine and surgery during the last calendar year and thus represent additions to the medical profession is shown in table 11. The compilation of this table includes candidates examined and licensed in 1958, some who were examined in previous years but whose licenses were withheld until 1958 pending completion of a required internship, citizenship, or other technicalities, and physicians not previously licensed in any state who were certified during the year on the basis of the examination of the National Board of Medical Examiners. The majority represented are recent graduates.

There were 7,809 additions to the medical profession in the United States and its territories and outlying possessions. In 1958, there were approximately 3,700 deaths of physicians reported to the offices of the American Medical Association. Deducting the number of deaths in 1958 from the number of licenses issued for the first time, it will be seen that there was a net increase of 4,109 in the physician population last year.

Among the 7,809 licentiates representing additions to the medical profession in the last calendar year were 6,155 who secured their licenses by examination and 1,654 by endorsement of credentials. The majority of the latter were diplomats of the National Board of Medical Examiners.

The number of first licentiates, arranged in nine geographical divisions, are compiled in table 12. The geographical divisions representing the greatest number of additions to the medical profession were the Middle Atlantic States with 1,708, the East North Central States with 1,447, and the South Atlantic States with 1,184. More than 400 were added in each of five other groups—Pacific 790, West North Central 784, West South Central 748, New England 470, and East South Central 446. The Mountain States added 129 and the territories and possessions 103.

In the 24 years from 1935 to 1958, inclusive, there were 157,891 new additions to the medical profession as determined by the number who received their first license. Figures for each year during this period are presented in table 13. Of the 157,891 in this group, 131,252 were licensed after written examination and 26,639 by endorsement of credentials. The total number of licenses issued in the same period (table 2) was 282,486.

Registration of Physicians, 1904-1958

A tabulation of total numbers of physicians registered for 55 years from 1904 to 1958, inclusive, is given in table 14. This study contains figures pertaining to the number of physicians examined and registered by written examination, the annual percentage of failures, the number registered annually by reciprocity or endorsement of credentials, and the total registered. The number of physicians registered annually from 1904 to 1933 shows slight fluctuation, except in 1918, when only 4,231 were licensed.

In the years since 1946, the numbers registered decreased annually until 1952, although they far exceeded the prewar totals. The last six years has shown an increase in the number of physicians registered, though the number registered in 1958 was slightly lower than in the previous year.

The highest percentage of failures was 21.7 in 1908. Many of the medical schools at that time were proprietary institutions operating for financial returns rather than the improvement of the medical curriculum. Beginning in 1915, the percentage of failures began to drop, reaching a low of 5.7% in 1930. Beginning in 1936, the percentage of failures began to rise, reaching another peak of 20.7 in 1940. This was the result of the increase in the number of foreign-trained physicians seeking licensure in the United States, many of whom were not successful after repeated attempts at licensure examinations. While the percentage of failures have been reduced somewhat in recent years, it still reflects the unsuccessful attempts of foreign-trained physicians, graduates of unapproved medical schools, and schools of osteopathy to secure licenses. The annual failure rate among graduates of approved medical schools is about 4%. This table refers to examinations given annually rather than to individuals examined. A candidate who fails more than once in a state in a given year is counted as one failure, but should he again fail in a succeeding year, this fact is computed among the failures for that year. Likewise, a successful candidate securing a license in more than one state in a given year is counted in both states and likewise is counted if he passed examinations in later years. The figures in this table give only a fair approximation of the number of physicians added to the profession.

Graduates of Approved Schools and Others Registered, 1922-1958

In table 15, the numbers of physicians registered since 1922 are grouped in two categories, namely, graduates of approved medical schools and others. In the computation of these figures, schools rated in classes A and B prior to 1928 by the Council on Medical Education and Hospitals of the American Medical Association are included in the first grouping. In 1928, the classification of medical schools in categories of A, B, and C by the Council was discontinued, and a list of approved medical schools has since been maintained. In the column headed

In 1958, there were 15,193 candidates registered, of whom 13,097, or 86.2%, were graduates of approved schools and 2,096, or 13.8%, were in the second group. In the 37 years recorded in this table, 375,756 candidates were registered, including 337,843 (89.9%) who were graduates of medical schools in the approved group and 37,913 (10.1%) who were other graduates.

Graduates of Unapproved Medical Schools Registered, 1953-1958

Recorded in table 16 are data regarding graduates of institutions that have not been approved by the Council on Medical Education and Hospitals of the American Medical Association. Figures are given for those licensed after written examination and those licensed by endorsement of credentials. The table also includes a column combining the figures for these two groups. They represent graduates of five unapproved medical schools, all but one of which are now extinct. The latter institution has obtained the status of an approved school. There were 240 graduates of unapproved medical schools registered from 1953 to 1958 inclusive, 79 by examination and 161 by endorsement of credentials. California, Florida, New York, and Texas licensed the greatest number of graduates of unapproved medical schools. Twenty-seven state boards were represented in the six-year period. In 1958, there were 32 licensed by 13 boards, 6 by examination, and 26 by reciprocity or endorsement. The numbers of such graduates appearing for licensure is steadily decreasing.

Graduates of Schools of Osteopathy Registered by Medical Examining Boards, 1953-1958

The number of graduates of schools of osteopathy granted the privilege of practicing medicine or surgery or both by 18 licensing boards from 1953 to 1958, inclusive, is given in table 17. There have been 1,708 such persons registered, 1,171 by examination and 537 without written examination. In 1958, 14 boards licensed osteopathic physicians to practice. Two boards licensed these graduates after examination only, and 4 licensed them only on the basis of reciprocity, while 8 boards licensed them after both methods. Following is a summary of the actions and regulations of the 18 boards providing for the licensing of osteopaths by the medical examining board.

In Colorado an osteopath receives a license to practice medicine and must meet the same requirements as for doctors of medicine. In Connecticut an osteopath registered by the osteopathic board may be licensed to practice medicine and surgery or both after examination by the medical examining board. Osteopaths in Delaware may be licensed as osteopathic physicians after successfully passing the examination of the medical board, except that the principles of osteopathy is given in the examination in place of materia medica.

The District of Columbia will permit any person engaged in the practice of osteopathy on or before Jan. 1, 1948, to file application for a license to practice osteopathy and surgery. To obtain such a license, an osteopath must pass all subjects of the medical examination and in addition must pass subjects in the practice of osteopathy. Osteopaths are eligible for licensure also by endorsement of the certificate issued by the National Board of Osteopathic Medical Examiners.

Since 1950, in Illinois, graduates of the Chicago College of Osteopathy are examined by the medical board and may receive medical licenses. In Indiana, under an amendment to the medical practice act in 1945, osteopaths are permitted to practice medicine, surgery, and obstetrics and to administer anesthetics, antiseptics, and narcotics. Persons who were licensed in osteopathy before 1945 may obtain from the medical board a license to practice osteopathy, surgery, and obstetrics.

Special examination and licensure is provided by the Healing Arts Act passed in Kansas in 1957. An osteopathic physician having graduated from an approved college of osteopathy after June 1, 1950, and who holds a valid license to practice osteopathy is eligible for licensure. Any person who on Jan. 1, 1957, was licensed to practice osteopathy and who on said date maintained an office and was actively engaged in the practice of osteopathy in Kansas may, if application is made prior to July 1, 1960, take a special examination.

In Massachusetts, for the purposes of registration, the D. O. degree is considered equivalent to the M.D. degree and applicants for licensure must meet the same requirements as M.D.'s. In New Hampshire, under the provisions of the medical practice act, osteopaths are granted the right to practice medicine and surgery. The New Jersey medical practice act provides that an osteopath licensed prior to Nov. 1, 1941, who has served for a period of two years as an intern or resident surgeon in an approved osteopathic or medical hospital, has completed a postgraduate course of two years in a college of osteopathy or medicine approved by the board, or has had at least three years of practice in a hospital approved by the board, can be admitted to an examination in pharmacology, therapeutics, and surgery. If successful, he can obtain a license to practice medicine and surgery.

In New York, a licensed osteopath who is an applicant for the right to use instruments for minor surgical procedures and to use anesthetics, antiseptics, narcotics, and biological products may be granted the right to practice medicine without limitation if his credentials satisfy the Board of Regents. If not, such applicants shall be required either to pursue further study or to pass a special examination.

The Ohio Medical Practice Act was amended in 1943 to provide that all graduates from osteopathic schools applying for the right to practice in the state must meet certain educational requirements and must pass certain examinations. One of the required examinations is in surgery. Those who qualify and pass all of the examinations are then given a license to practice osteopathic medicine and surgery. Those in practice and licensed under a more limited law in effect prior to 1943 can secure a license to practice osteopathic medicine and surgery by meeting certain additional requirements, including postgraduate work and the passing of additional examinations.

In Oregon, osteopaths who meet certain requirements are granted the right to practice in the subjects covered by the medical examination, with the exception of the practice of medicine or materia medica and therapeutics. In South Dakota, osteopaths may be licensed to practice medicine, surgery, and obstetrics. This is an unrestricted license. Texas issues only one license, which is unrestricted in scope.

In Virginia, two classes of osteopaths are licensed. If a candidate takes the same examination as an M.D., substituting the practice of osteopathy for the practice of medicine, he is licensed to practice osteopathy with the use of surgery and drugs. However, if he takes an examination without the subjects of surgery and materia medica, he is licensed to practice osteopathy without the use of drugs or surgery.

The Wisconsin law, amended in 1950, provides that an osteopath, licensed in the state may obtain a license to practice medicine and surgery by completing a refresher course in materia medica and pharmacology consisting of not less than 64 hours of lecture and 60 hours of laboratory work and by passing an examination in these subjects. Osteopaths not licensed in the state may apply to take the same examination as physicians. If successful, they will be granted licenses to practice medicine and surgery. In Wyoming, the statutes contain no specific provision for the licensing of osteopaths. The medical practice act provides that the certificate issued to all physicians shall be deemed a license to practice medicine in all branches in which the applicant has taken an examination.

Enactment and Operation of Medical Practice Act

An attempt was made this year to obtain from each licensing board the year when the first medical practice act was enacted and the year when the first examining board was established under the medical practice act. These data are given in table 18. Not all states were able to provide this information. It is to be hoped that this table can be presented in more complete form when next this study is made.

Preprofessional Training Requirements of Licensing Boards

In order to provide an opportunity for medical students to gain a broad educational background, the Council on Medical Education and Hospitals of the American Medical Association recommends four years of preprofessional college training. Since January, 1953, the minimum requirement for admission to an approved medical school has been three years of college work, with the provision that rarely and only under exceptional circumstances will an approved medical school be justified in admitting a superior student with only two years of college preparatory work.

The preprofessional requirements of medical licensing boards are indicated in table 19. Seven boards specify that no preprofessional requirement is mentioned in the medical practice act. Twenty-one boards reported a three-year requirement. In others, the law specifies at least two years of college work. No board specifies in detail the number of hours that must be devoted to the subjects of the preprofessional curriculum, although 19 boards report that this training must include certain subjects, such as English, physics, chemistry, biology, and a foreign language. The candidates appearing for medical licensure are graduates of all years, and the seeming lack of conformity with accepted standards as promulgated by the Council on Medical

Education and Hospitals of the American Medical Association and the Association of American Medical Colleges is due to the fact that initiation of the current three-year minimum requirement for all candidates appearing for licensure would eliminate many graduates of earlier years. In practice, the boards in granting licensure to a graduate of an approved medical school accept the premedical training required in the year the candidate was admitted to a medical school.

Approval of Medical Schools

Seven licensing boards maintain their own list of approved medical schools in the United States and Canada. Twenty-six boards require applicants for licensure from approved medical schools in the United States or Canada to be graduates of medical schools approved by the Council on Medical Education and Hospitals. Two boards require membership in the Association of American Medical Colleges. Twenty boards specify that schools must be approved by the Council and be in membership in the Association of American Medical Colleges. In 16 instances the requirement is specified in the medical practice act, 37 boards reported that it is a formal regulation, and 2 indicated that it was an informal policy. In actuality, all approved medical schools are both approved by the Council and in membership in the Association of American Medical Colleges.

Required Internships

One year of internship, as a prerequisite to licensure, is required by the licensing boards of 32 states, the District of Columbia, Canal Zone, Guam, Hawaii, Puerto Rico, and the Virgin Islands. Nine boards specify that the internship must be a rotating service. Rhode Island will accept a straight internship if it is a part of a three-year approved residency. New Jersey reports that a one-year rotating service, or two years of straight internship, or a two-year residency in a specialty will meet the requirement of hospital service. Postgraduate training is accepted in lieu of deficiencies in the requirement of a rotating internship in Alaska after seven years from the date of graduation from medical school. Missouri requires the internship for reciprocity applicants only. Those licensing boards that require an internship as a prerequisite for licensure are listed in table 20.

1. Not specified by law.
2. Entrance requirement prescribed by accrediting agencies.
3. Three years for applicants matriculating after Jan. 1, 1954.
4. One year prior to 1919, two years subsequent to 1947, including courses in physics, chemistry, and biology.
5. Premedical training must include courses in physics, chemistry, biology, English, and a foreign language.

6

7 ysics, chemistry, and biology must be

8 lude courses in English, physics, chemistry (general and organic), and biology.

Temporary and Educational Permits, Limited and Temporary Licenses, or Other Certificates Issued by State Licensing Boards

Thirty-eight boards provide for the issuance of temporary and educational permits, limited and temporary licenses, or other certificates. The terms for the issuance of such certificates vary. This limited registration may apply to hospital training, to those ineligible for licensure who seek further educational training, or for regular practice until the next regular session of the licensing board. A list of these states and information on the length of validity of this special registration are shown in table 21.

Licensure Requirements for Interns and Residents in Hospitals

In general, physicians serving internships are not required to be licensed in the state in which the hospital where they are interning is located. Indiana and Puerto Rico have such a requirement. Delaware, the District of Columbia, and New Jersey permit a service of two years without licensure, and Florida permits a three-year service before licensure. Other boards have a requirement of registration with the licensing board or a stipulation that the physician must be eligible for licensure. The states which require some form of registration for interns are listed in table 22.

Thirty-one boards require that physicians serving residencies in hospitals must be licensed or registered in the state. Twenty-three boards stipulate that registration must be in the form of a regular license or a temporary certificate for the term of the residency. Seven boards do not require licensure but stipulate some form of registration with the licensing board. The regulations of each of the licensing boards that exact some requirement of those engaged in residency training are given in table 23.

1. Internship must be a rotating service.
2. For reciprocity applicants.
3. One year rotating service or two years of straight internship or two-year residency in a specialty.
4. After seven years from date of graduation from medical school, postgraduate training accepted in lieu of deficiencies in a rotating internship.
5. Straight internship accepted if part of a three-year approved residency.

TABLE 21.—*Temporary and Educational Permits, Limited and Temporary Licenses, or Other Certificates Issued by State Licensing Boards*

Alaska	Temporary permits issued while processing permanent licensure to summer cannery physicians and to physicians in the armed forces on short periods with private physicians and for locum tenens work.
Arizona	Temporary permits issued on basis of community emergency.
Arkansas	Temporary permits are granted reciprocity applicants until regular board meeting.
Connecticut	Educational permits granted to graduates of unapproved medical schools to serve in approved hospital training programs.
Delaware	Temporary emergency license upon proved emergency, one year, subject to renewal, and for locum tenens practice (2 to 4 months).
Georgia	Permit until board meets. Permits for aliens to practice in state institutions or medical schools.
Guam	Restrictive certificate to permit medical employees of federal contractors to practice in the discharge of their official duties.
Idaho	To candidates holding certificate of National Board of of Medical Examiners or licensed by written examination in another state until next meeting of board and to residents in hospitals.
Illinois	Temporary certificates for residency training for applicants who are not qualified for permanent registration. Permit issued for service in state hospitals to physicians eligible for licensure.
Indiana	Temporary license pending next examination for graduates of approved medical schools. Temporary reciprocal license for six months.
Iowa	Resident physicians licenses are issued for a period of not more than seven years for service in a hospital approved by the board.
Kansas	Temporary permit until next board meeting providing application is in proper form for license.
Kentucky	Temporary permits issued to applicants by endorsement for six-month period to serve until investigations completed and meeting of board. Limited licenses for one year, renewable for special place, purpose, and time.
Louisiana	[illegible] to physicians possessing [illegible] file application for examination [illegible] Louisiana between the [illegible] meetings of the board. [illegible] next meeting of the board.
Maine	Temporary licenses granted for residency training for one year. Must be an American citizen and a graduate of an approved medical school.
Massachusetts	Limited registration covering appointment as intern, resident, or fellow in a specific hospital or as assistant in medicine while a student in medical school.
Michigan	Temporary license for residency and postgraduate training program renewable annually not to exceed five years.
Minnesota	Limited license for duration of residency.
Mississippi	Temporary permit for practice until next board meeting pending permanent license.
Montana	In unusual circumstances only.
Nevada	Temporary permit for one year for residency training.
New Hampshire	Temporary license for five years to foreign physicians. Permanent license issued upon becoming citizen of the United States.
New Jersey	Temporary license for four months may be renewed at monthly intervals not to exceed one year.
New Mexico	Institutional permits for practice in state hospitals only. Temporary permits issued until next board meeting.
New York	Temporary certificate for two years for residency training except in state, mental and municipal hospitals.
North Carolina	Limited license issued for duration of residency.
North Dakota	Temporary permit for United States and Canadian graduates until next board examination.
Oklahoma	Temporary licenses for one year for residency training in approved hospitals.
Pennsylvania	Postgraduate certificate issued for residency training if licensed in any state or territory or the United States or Canada or hold the certificate of the National Board of Medical Examiners.
Puerto Rico	Special permit may be granted.
Rhode Island	Temporary permit for one year for interns, residents, and house officers in hospitals.
South Carolina	Temporary permits for interns and residents renewable annually not to exceed five years.
South Dakota	Temporary license issued for graduates of foreign medical schools for four years for practice in emergency medical areas for a period of four years before permanent license is issued.
Texas	Temporary permit issued until next board meeting.
Virginia	Temporary permit issued until next board meeting for reciprocity applicants.
Virgin Islands	Temporary certificates issued to military service personnel on duty and to municipal personnel until next license examination.
West Virginia	Temporary permits issued until next board meeting to qualified applicants.
Wisconsin	Temporary educational permit for graduates of foreign medical schools not recognized by board for licensure.

Schedule of Written Examination Dates and Reciprocity Meetings

The schedules of dates for written examination and meetings or oral examination for the issuance of licenses by reciprocity or by endorsement of credentials is given in table 24. In most instances, written examinations are scheduled twice annually and reciprocity meetings quarterly or as soon as the application for licensure can be processed. In those states requiring a basic science certificate for licensure, dates of the examination or reciprocity meetings are arranged to coincide closely with the examination and meeting dates of the boards of examiners in the basic sciences.

TABLE 22.—*Licensure, Registration, or Other Requirements for Interns*

Licensure	Other Requirements
Indiana	Colorado[6]
Puerto Rico	Delaware[2]
	District of Columbia[2]

	Rhode Island[5]
	South Carolina[5]
	Texas
	Virginia[4]
	West Virginia[4]

---

[1] Must register every six months with State Board of Health and may serve for a period of three years without licensure.

[2] May serve for two years without licensure.

[3] Limited registration granted.

[4] Graduates of unapproved foreign medical schools must obtain permission from board.

[5] Temporary permit required.

[6] May serve for an aggregate period not to exceed four years; required to register with licensing board annually.

Medical Licensure Fees

Table 25 lists for each licensing board the fee charged for registration by examination and also by reciprocity or endorsement of credentials. The examination boards tend to be uniform, the majority of the boards charging a fee of $25. The fee for a license without examination varies from $5 to $200. Three states have a lower fee for those being certified on the basis of the certificate of the National Board of Medical Examiners than for candidates licensed by endorsement of state license. One state exacts the same fee as the reciprocating state fee for such a license.

Licensure on Government Credentials

Few states have provision in their medical practice act for the acceptance of credentials issued by the federal government or the armed services as a basis for licensure without examination. Nine boards —Alabama, Arizona, California, Delaware, Illinois, Pennsylvania, Texas, Utah, Vermont, and Wisconsin —have indicated that in their discretion they may accept such credentials under varying regulations.

Annual Registration

Forty boards require physicians to register their licenses annually or biennially. This requirement applies in some states whether or not the physician is engaged in practice in the state. In table 26 are listed the licensing boards that exact this requirement and the fee charged for such registration. The fee ranges from $1 to $10. Five states have a nonresident fee. Guam does not charge a fee. In Florida physicians are required to register with the state board of health, while New York, North Carolina, and West Virginia require biennial registration.

Citizenship Requirements for Permanent Licensure

Table 27 lists the United States citizenship requirements for permanent licensure by the 55 licensing boards of the United States and its territories and possessions. Eight boards have no citizenship requirement, 17 states require that the applicant declare his intention of becoming a citizen, and 30 states require full citizenship.

TABLE 23.—*Licensure, Registration, or Other Requirements for Residents*

[1] May serve one year without licensure.

[2] May be required by hospitals.

[3] Applicants who wish to serve residencies in Illinois hospitals and who are not eligible for permanent registration may apply for temporary certificates which are issued without examination. Also permits to practice in State hospitals to applicants qualified for examination.

[4] Temporary license for one year.

[5] Limited registration granted.

[6] Limited license for duration of residency.

[7] Temporary certificate for two years for residents, except in state mental and municipal hospitals.

[8] Postgraduate certificate issued for residency training if licensed in any state or territory of the United States or Canada or hold the certificate of the National Board of Medical Examiners.

[9] May serve for an aggregate period not to exceed four years. Required to register with licensing board annually.

[10] Three years without licensure. Must register every six months with board of health.

[11] Resident physician's licenses are issued for a period of not more than seven years for service in a hospital approved by the board.

[12] Graduates of unapproved foreign medical schools must obtain permission from board.

[13] May serve two years without licensure.

[14] Temporary license for residency and postgraduate training renewable annually not to exceed five years.

[15] Registration with licensing board required.

Registration Policies for Citizens of Canada by Licensing Boards in the United States

The licensing boards of the United States and its territories and possessions have reported that they will accept graduates of approved medical schools of Canada for licensure by examination on the same basis as graduates of approved medical schools of the United States. Table 28 records the registration policies for citizens of Canada. Few states indicate that they will accept Canadian registration for licensure by reciprocity or endorsement. Modifications are made in the citizenship requirement for candidates from Canada. This table shows for each state whether United States citizenship is a requirement, whether the candidate must declare his intention of becoming a citizen, and if no citizenship requirement is exacted.

Licensure of Foreign-Trained Physicians

Since 1950, the Council on Medical Education and Hospitals of the American Medical Association and the Executive Council of the Association of American Medical Colleges have published a list of foreign medical schools whose graduates are recommended for consideration on the same basis as graduates of approved medical schools in the United States and Canada. This list has always been offered as an advisory list for the use of state licensing boards, hospitals, specialty boards, and other organizations in the United States concerned with the evaluation of medical credentials and qualifications of graduates of foreign medical schools. These same organizations have always been advised that the list was acknowledged to be a tentative one and that the position of the Councils with respect to the foreign medical schools not listed has been that they neither approve nor disapprove of them.

TABLE 24.—*Schedule for Written Examination and Issuance of Licenses by Reciprocity or Endorsement of Credentials*

	Written Examinations	Licenses by Reciprocity or Endorsement Issued

[a] Endorsement of certificate of National Board of Medical Examiners, $25.

[b] Same as reciprocating state fee for such a license.

[c] Endorsement fee, $50.

[d] Endorsement of certificate of National Board of Medical Examiners, $10.

In the years since the initial publication of this list, the number of graduates of foreign medical schools coming to the United States on either temporary or permanent visas has increased tremendously. The vast majority of physicians now entering this country either for further study as interns or residents or for permanent stay and medical licensure have received their medical degrees from medical schools other than those listed.

TABLE 26.—*States Requiring Annual Registration*

State	Fee	State	Fee
Arizona	$ 5.00	Nebraska	$ 3.00

This summary should be supplemented by direct communication with the secretary of the licensing board of the state in which the physician is interested.

---

* See separate table applicable to Canadian citizens.

** The withdrawal of the listing of foreign medical schools by the American Medical Association and the Association of American Medical Colleges, and its accompanying recommendation is to become effective as of January 1, 1960.

x Implies yes.

D Declaration of intention to become citizen of the United States.

Additional Requirements

Alabama. Candidate is eligible if he is certified by the National Board of Medical Examiners and approved.

California. Two-year internship in an approved hospital in the United States, one of said years being in California.

Colorado. Credentials must be submitted in original form and accompanied by translation and will be directly verified or documents should bear evidence of being visaed by the U. S. Consul in the [illegible] ool of graduation is or was located. [illegible] of foreign medical schools not on accepted [illegible] by E. C. F. M. G. before serving as interns or residents. Minimum of three years of hospital training in approved hospital in United States or Canada required, one year of which must be in general medicine.

Delaware. Residence for one year required.

Georgia. Reciprocity applicants may furnish certification of passing examination of E. C. F. M. G. in lieu of acceptable medical school, and applicants for examination are given consideration on an individual basis.

Hawaii. Diplomates of National Board eligible on reciprocity basis.

Illinois. Limited license for practice in hospitals maintained by the state.

Indiana. Graduation from medical school approved by Indiana board, plus repetition of senior year in approved medical school in United States or two years' postgraduate work in approved hospital in the United States. Postgraduate work must be obtained in states other than Indiana.

Iowa. Requirements include (1) medical diploma, (2) three years of residency training approved by the board, and (3) recommendation of the Educational Council of Foreign Medical Graduates.

Kansas. Certificate from medical college specifying in detail the physical equipment of the school, the curriculum, current catalog showing courses of study, and certificate that the college is recognized by authorities of such foreign country as qualifying its graduates for practice therein; diploma from such college; certificate of licensure in the country where graduated; one year of internship in the United States or certificates from reputable practitioners or teachers licensed in United States who graduated from same school.

Kentucky. Applicant required to complete at least five years' training in the United States in an institution approved by the board and to have successfully passed examination of National Board of Medical Examiners.

Maryland. Graduates of recommended foreign medical schools may be admitted to examination after completion of one year of internship or residency in an approved hospital in the United States if their credentials are approved and have submitted at least two letters from the hospital authorities recommending them as to professional ability and moral character.

Graduates of foreign medical schools not on the recommended list who obtained the medical degree after Jan. 1, 1940, are not accepted unless they have served at least three years as an intern or resident in approved hospitals in the United States and have submitted at least two letters from each hospital recommending them as to their professional ability and moral character.

Graduates of foreign medical schools, before Jan. 1, 1940, whose schools were known to have had acceptable standards at the time of graduation may be considered if their credentials and professional experience in the United States are acceptable.

Ability to write and speak the English language clearly is a primary requisite.

Massachusetts. Must furnish documentary evidence that education is equivalent to that of graduates of United States medical schools and shall be required to take examination of National Board of Medical Examiners who shall certify that the applicant has successfully passed said examination.

Minnesota. Two-year internship is required.

New Hampshire. Diplomates of National Board of Medical Examiners eligible on endorsement basis. Temporary license valid until citizenship is completed may be given. Considered on an individual basis.

New Jersey. Internship completed in foreign countries after July 1, 1934, not acceptable. Acceptance limited to schools recognized by the board. Considered on an individual basis. After Jan. 1, 1955, must have minimum of three years' training in a hospital approved by the board.

North Carolina. At the discretion of the Board.

Ohio. Graduates of schools of Continental Europe after 1943 are eligible if on accepted list. If not licensed in a foreign country must have one year in hospital in the United States; if not on accepted list, two years of training in an approved hospital in the United States. Considered on an individual basis.

Oregon. The board at its discretion may utilize the facilities of the *Educational Council for Foreign Medical Graduates.* Must show evidence of internship and/or residency of not less than two years in not more than two hospitals approved for such training. Less than an unqualified recommendation from the heads of these training programs shall preclude further consideration.

Pennsylvania. Graduates of foreign medical schools, with the exception of those who matriculated before Oct. 1, 1957 in the schools approved by the board or those licensed by examination in another state, are required to pass the examinations of the Educational Council for Foreign Medical Graduates.

Rhode Island. E. C. F. M. G. certification required for those who begin to qualify after Jan. 1, 1958.

South Dakota. Applicant required to practice in an emergency area for four years under a temporary license and reappear before the board for permanent licensure. After July 1, 1955, only those cleared through IRO will be eligible.

Tennessee. All applicants must be from medical schools whose curriculum equals that of the University of Tennessee. Each applicant considered on an individual basis.

Vermont. Certification by Educational Council for Foreign Medical Graduates or National Board of Medical Examiners required.

Virgin Islands. Residence of six months required.

Virginia. Applicant must be licensed to practice medicine and surgery in country in which school of graduation is located or must have completed the course of study and passed examinations equivalent to those required for a diploma or license conferring such full right to practice. Two years of internship in approved hospital in the United States or Canada within the past five years prior to application or one year of study in an approved medical school in lieu of one year of the internship. If citizenship is not acquired within seven years after licensure, the license automatically becomes void.

West Virginia. Applicant must be resident of the state for three years preceding application and recommended by local society. Certification by Educational Council for Foreign Medical Graduates considered.

Wisconsin. 1953 Legislature established One Year Temporary Educational Permit, which authorizes graduates of unapproved foreign schools to obtain residency training in [illegible] renewed for two additional years. Educ [illegible] Medical Graduates certification accepted [illegible] cedure.

have been on the list. Rather, this action reflects the Councils' inability to acquire and maintain a continuing, adequate knowledge of the educational programs of the foreign medical schools whose graduates come to the United States.

The two Councils now recommend that agencies in the United States concerned with the medical qualifications of graduates of foreign medical schools consider certification by the Educational Council for Foreign Medical Graduates as evidence that the recipient of such certification is possessed of medical knowledge comparable to that expected of graduates of approved medical schools in the United States and Canada. These two Councils further recommend that such certification be considered as evidence of the quality of medical training offered by the medical school attended by the holder of a certificate at the time of his graduation.

The present requirements for foreign-trained physicians seeking medical licensure in the United States and its territories and possessions are given in table 29. This chart was developed in an effort to assist the foreign-trained physician seeking licen-

sure in the United States. While an attempt has been made to present the situation as it exists, the table is intended to give only a summary of existing requirements. Persons interested in licensure should supplement these data by communicating with the licensing boards. Medical licensure in the United States is a "state right" and is entirely under the jurisdiction of the governments of the individual states. The power to license physicians is exercised through the medical licensing board of each state, territory or possession. There is also available from the office of either Council a pamphlet entitled "The Present and Future Status of Foreign Medical School Credentials in the United States" which contains helpful information to foreign-trained physicians.

Table 30 records the number of graduates of foreign faculties of medicine examined for medical licensure by 43 boards in 1958. The figures include both American and foreign-born physicians educated abroad. Graduates of the medical schools in the Philippines, New Zealand, 13 South and Central American countries, 26 countries in Europe, and 15 countries in Asia were represented at examinations. The number totaled 2,567. Graduates of 231 medical schools and four licensing corporations were examined. The number who were successful was 1,518; failures numbered 1,049, or 40.9%. More than 75 graduates each from the University of Cuba, Munich, Athens, Rome, Mexico, and Geneva were tested in 1958, and more than 20 graduates from 33 other schools were examined. The following eight states examined the greatest number of foreign-trained physicians.

	Examined	Passed	Failed, No.	Failed, %
New York	614	352	262	42.7
Illinois	438	160	278	63.5
Connecticut	194	136	58	29.9
Virginia	189	95	94	49.7
Maryland	180	114	66	36.7
Ohio	166	71	95	57.2
California	165	98	65	39.9
New Jersey	135	111	24	17.8

Table 31 presents the number of graduates of foreign faculties of medicine examined for medical licensure in the United States in 29 years (1930-1958). In 1936 the number of foreign-trained physicians seeking licensure in the United States began to increase, and by 1940 over three times as many were tested as in 1936. Beginning in 1944, the number examined began to decrease until 1951, when there was a noticeable increase. In each succeeding year the number of examined has increased. In 1958, the increase over the previous year was 268. At no time in the 29-year period did fewer than 30% fail in a given year.

In table 32 figures are given for 13 years showing the number of foreign-trained physicians licensed by each state board, both after written examination and by endorsement of credentials. Aggregate figures are given for the years 1946-1953, inclusive,

and for each individual year from 1954 to 1958. While table 31 reflects the candidates registered after examination only and indicates the percentage failing in each year, table 32 records the total licensed in each state. In the period shown there were 9,317 licenses issued to foreign-trained physicians after written examination and 2,033 by endorsement of credentials. The total number of licentiates in both groups registered was 11,350.

Represented in table 33 are figures regarding the foreign-trained physicians registered in 1958 who were not previously licensed in the United States and who, therefore, are additions to the medical profession. There were 1,166 in this group, of whom 1,129 were licensed by written examination and 37 by endorsement of credentials. Comparative figures for eight previous years together with the figures for 1958 are given in table 34. In eight years (1950-

CORRESPONDING OFFICERS OF BOARDS OF MEDICAL EXAMINERS IN THE UNITED STATES, TERRITORIES, AND OUTLYING POSSESSIONS

Alabama	Dr. D. G. Gill, Secretary, State Office Building, Montgomery 4.
Alaska	Dr. W. M. Whitehead, Secretary, 172 S. Franklin St., Juneau.
Arizona	Mr. Robert Carpenter, Executive Secretary, 826 Security Bldg., Phoenix.
Arkansas	Dr. Joe Verser, Secretary, Harrisburg.
California	Dr. Louis E. Jones, Secretary, Room 536, 1020 N St., Sacramento.
Canal Zone	Dr. Eric R. Osterberg, Health Director, Balboa Heights.
Colorado	Dr. John B. Farley, Secretary, 715 Republic Bldg., 1612 Tremont Place, Denver 2.
Connecticut	Dr. Stanley B. Weld, Secretary, 160 St. Ronan St., New Haven.
Delaware	Dr. Joseph S. McDaniel, Secretary, Professional Bldg., Dover.
District of Columbia	Mr. Paul Foley, Deputy Director, 1740 Massachusetts Ave., N.W., Washington.
Florida	Dr. Homer L. Pearson, Secretary, 901 N.W. 17th St., Miami 36
Georgia	Mr. Cecil L. Clifton, Secretary, 224 State Capitol, Atlanta 3.
Guam	Dr. John E. Kennedy, Secretary, Marianas Islands, Agana.
Hawaii	Dr. I. L. Tilden, Secretary, 1020 Kapiolani St., Honolulu.
Idaho	Mr. Armand L. Bird, Executive Secretary, 364 Sonna Bldg., Boise.
Illinois	Mr. Fredric B. Selcke, Superintendent of Registration, Capitol Bldg., Springfield.
Indiana	Miss Ruth V. Kirk, Executive Secretary, 538 K. of P. Bldg., Indianapolis.
Iowa	Mr. Ronald V. Saf, Executive Secretary, State Office Building, Des Moines 19.
Kansas	Dr. F. J. Nash, Secretary, New Brotherhood Bldg., Kansas City.
Kentucky	Dr. Russell E. Teague, Secretary, 620 South Third St., Louisville 2.
Louisiana	Dr. Edwin H. Lawson, Secretary, 930 Hibernia Bank Bldg., New Orleans 12.
Maine	Dr. Stephen A. Cobb, Secretary, Sanford.
Maryland	Dr. Frank K. Morris, Secretary-Treasurer, 1211 Cathedral St., Baltimore 1.
Massachusetts	Dr. David W. Wallwork, Secretary, State House, Room 37, Boston 33.
Michigan	Dr. E. C. Swanson, Executive Secretary, 118 Stevens T. Mason Bldg., West Michigan Ave., Lansing 8.
Minnesota	Dr. F. H. Magney, Secretary, 230 Lowry Medical Arts Bldg., St. Paul 2.
Mississippi	Dr. R. N. Whitfield, Assistant Secretary, Old Capitol, Jackson 13.
Missouri	Mr. John A. Hailey, Executive Secretary, State Capitol Building, P. O. Box 4, Jefferson City.
Montana	Dr. Thomas L. Hawkins, Secretary, 555 Fuller Ave., Helena.
Nebraska	Mr. R. K. Kirkman, Director, Room 1009, State Capitol Build., Lincoln 9.
Nevada	Dr. George H. Ross, Secretary, 112 North Curry St., Carson City.
New Hampshire	Dr. Edward W. Colby, Secretary, 61 South State St., Concord.
New Jersey	Dr. Royal A. Schaaf, Secretary, 28 West State St., Trenton.
New Mexico	Dr. R. C. Derbyshire, Secretary, 227 East Palace Ave., Santa Fe.
New York	Dr. Stiles D. Ezell, Secretary, 23 South Pearl St., Albany 7.
North Carolina	Dr. Joseph J. Combs, Secretary, 716 Professional Bldg., Raleigh.
North Dakota	Dr. C. J. Glaspel, Secretary, Box 228, Grafton.
Ohio	Dr. H. M. Platter, Secretary, 21 West Broad St., Columbus 15.
Oklahoma	Dr. E. F. Lester, Secretary, 813 Braniff Bldg., Oklahoma City.
Oregon	Mr. Howard I. Bobbitt, Executive Secretary, 609 Failing Bldg., Portland 4.
Pennsylvania	Mrs. Margaret G. Steiner, Secretary, Box 911, Harrisburg.
Puerto Rico	Mr. Joaquin Mercado Cruz, Secretary, Box 9156, Santurce.
Rhode Island	Mr. Thomas B. Casey, Administrator, 366 State Office Bldg., Providence.
South Carolina	Dr. Harold E. Jervey Jr., Secretary, 1329 Blanding St., Columbia.
South Dakota	Mr. John C. Foster, Executive Secretary, 300 First National Bank Bldg., Sioux Falls.
Tennessee	Dr. H. W. Qualls, Secretary, 1635 Exchange Bldg., Memphis 3.
Texas	Dr. M. H. Crabb, Secretary, 1714 Medical Arts Bldg., Fort Worth 2.
Utah	Mr. Frank E. Lees, Director, 324 State Capitol Building, Salt Lake City 1.
Vermont	Dr. F. J. Lawliss, Secretary, Richford.
Virgin Islands	Dr. Rudolph U. Lanclos, Secretary, Charlotte Amalie.
Virginia	Dr. K. D. Graves, Secretary, 631 First St., S.W., Roanoke.
Washington	Mr. Thomas A. Carter, Administrator, Capitol Building, Olympia.
West Virginia	Dr. Newman H. Dyer, Secretary, State Office Building, No. 3, Charleston 5.
Wisconsin	Dr. Thomas W. Tormey Jr., Secretary, 1140 State Office Bldg., 1 West Wilson St., Madison.
Wyoming	Dr. Franklin D. Yoder, Secretary, State Office Building, Cheyenne.

1958) there were 6,483 foreign-trained physicians who were added to the physician population of the United States, 6,483 obtaining licensure by written examination, and 240 by endorsement of credentials.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Basic science laws currently exist in 21 states and the District of Columbia. The enactment of a basic science law provides for the establishment of a state board of examiners in the basic sciences underlying the practice of the healing art, to provide for its organization and powers, to provide that certificates by that board be a prerequisite to eligibility for examination for licenses to practice the healing art, and to define the healing art. Basic science boards have no licensing powers. The healing art, as defined in the statutes, includes any system, treatment, operation, diagnosis, prescription, or practice for the ascertainment, cure relief, palliation, adjustment, or correction of any human disease, ailment, deformity, injury, or unhealthy or abnormal physical or mental condition.

Table 35 lists the states where basic science laws exist and the year of enactment. Minnesota, Nebraska, and Washington, in 1927, were the first states to effect such legislation; Kansas under a "Healing Arts Act", in 1957, was the last state to require such certification.

The specific basic sciences designated in the legislation vary with the different laws. All boards examine in anatomy, pathology, and physiology, and the majority include bacteriology and chemistry. Ten include Hygiene, two diagnosis, and one requires public health. Table 36 lists the basic science boards and the subjects in which examinations are required.

Table 35.—*States Having Basic Science Laws and Year of Enactment*

Alaska	1946	Nebraska	1927
Arizona	1936	Nevada	1951
Arkansas	1929	New Mexico	1941
Colorado	1937	Oklahoma	1937
Connecticut	1925	Oregon	1934
District of Columbia	1929	Rhode Island	1940
Florida	1939	South Dakota	1939
Iowa	1935	Tennessee	1943
Kansas	1957	Texas	1949
Michigan	1937	Washington	1927
Minnesota	1927	Wisconsin	1925

The laws in some states provide for certification without examination by exemption, waiver, reciprocity, or endorsement. The credentials acceptable for certification by one of these methods are outlined in table 37.

The results of examinations given and the number of certificates issued on the basis of waiver, exemption, reciprocity, or endorsement, as reported by the basic science boards during 1958, are shown in tables 38 and 39. The laws generally do not specify that a candidate reveal his school of practice but were developed for the purpose of insuring, insofar as possible, that all individuals who enter into the area of the healing arts have what is considered to be an adequate preparatory background. Table 38 records the total number of candidates reported by the several boards as having been examined and the number who passed and failed. No attempt has been made to differentiate the schools of the healing arts represented by the candidates examined or certified. Twelve boards either had no failures or did not report figures for failures. The percentage of candidates failing is given for those states that did submit these data.

Wisconsin	x	..	..	x	..	x	x	..

The 22 boards in operation in 1958 examined 4,600 candidates and granted certificates of proficiency in the basic sciences by written examination to 3,592 individuals. In addition, as noted in table 39, there were 2,677 certificates issues by reciprocity, endorsement, exemption, or waiver by 21 boards. The number of applicants registered with or without examination in 1958 was 6,269. Of these, Texas issued 741, Florida 666, Michigan 571, and Wisconsin 508. Other states ranged from Alaska with 22 to Arkansas with 456.

In the 32 years since the enactment of the first such laws (table 40) 95,069 certificates in the basic sciences have been issued, 66,282 by examination and 29,787 by reciprocity, endorsement, exemption, or waiver. The percentage of failures in this period was 20.5.

The fees for certification in the basic sciences in the states requiring such certification are given in table 41. Examination and endorsement meetings are held in most instances semiannually, although some boards meet quarterly. THE JOURNAL publishes semimonthly the future dates of examination and reciprocity or endorsement meetings of all basic science boards.

In 1958 there were 4,600 examinations given by basic science boards; 3,592 were successful and 1,008 were unsuccessful, thereby failing to give evidence of basic preparation adequate to qualify for further consideration for licensure. Figures on how many individuals these 1,008 failures represent were not available for this report. The boards are not uniform with respect to repetition of examinations

TABLE 37.—*Reciprocity, Endorsement, Waiver, or Exemption Policies of Basic Science Boards*

Alaska

Physicians are accepted on reciprocity from those states with which the board of medical examiners has established reciprocal agreements.

Arizona

A reciprocal certificate issued on the basis of a basic science certificate that has been obtained by an examination before the issuing board and provided that at least four subjects were passed at one sitting unless the state in question examines in fewer than four of the six subjects required by the Arizona law. Reciprocity will be extended to those applicants who were licensed to practice in a state prior to the passage of the basic science law of that state.

Arkansas

Reciprocity on the basis of written examination taken before all states having basic science laws except Florida, Iowa, and Tennessee. The credential of the National Board of Medical Examiners is acceptable for reciprocal registration. State medical board examinations in the basic science subjects are acceptable when they are deemed to be equivalent to the Arkansas basic science examination.

Colorado

Reciprocity as to examination with the following basic science boards: Alaska, Arizona, Arkansas, District of Columbia, Kansas, Michigan, Minnesota, Nebraska, Nevada, New Mexico, Oklahoma, Oregon, Rhode Island, South Dakota, Tennessee, Texas, and Washington.

Reciprocity as to examination with the Iowa Basic Science Board is granted to those candidates having made original application to that board on or before June 1, 1949. Candidates making application after that date and holding a certificate must meet the minimum requirements, i.e., that the candidate pass an examination in the basic sciences under a basic science board and that he pass, at one sitting, at least four of the five subjects given by the basic science board of Colorado, with subsequent passing of the fifth subject.

With Connecticut and Wisconsin there is reciprocity as to examination in the subjects of anatomy, physiology, and pathology. Candidates from these states are required to pass the examinations in chemistry and bacteriology.

Connecticut

No reciprocity with other basic science boards. Certification by endorsement obtainable by diplomates of the National Board of Medical Examiners or to candidates holding a license obtained by examination in another state. The latter is acceptable only after three years' professional activity.

District of Columbia

Reciprocity has not been established with the basic science boards. The basic science board may exempt an applicant. All applications are considered on an individual basis. Basic science examination as part of a medical license used for reciprocal licensure would be acceptable if licensure was granted.

Florida

No reciprocity, waiver, or exemption policies.

Iowa

All applications considered on an individual basis. May accept examination results of other boards if, in the opinion of the Iowa board, the examination is considered equal to that of the Iowa board.

Kansas

No formal reciprocal agreements. Board will consider on an individual basis acceptance of examinations given by other basic science board, state medical boards, and part 1 of the examination of the National Board of Medical Examiners.

Michigan

Certificates issued by examination are accepted for registration by waiver from the basic science boards of Alaska, Arizona, Arkansas, Colorado, District of Columbia, Iowa, Kansas, Minnesota, Nebraska, Nevada, New Mexico, Oklahoma, Oregon, Rhode Island, South Dakota, Tennessee, Texas and Wisconsin.

Applicants who present certificates from the Wisconsin Basic Science Board are examined in bacteriology and chemistry.

The Michigan Board may accept, in lieu of its own examination, the basic science portion of the examination given by any legally constituted examining or licensing board in the healing arts it such examination is equal or equivalent to the examinations given by the Michigan Board.

Minnesota

Reciprocity on an automatic basis with the basic science boards of Colorado, Nebraska, Oregon and Tennessee (after Feb. 9, 1950), and on the basis of having passed part 1 of the examination of the National Board of Medical Examiners.

Reciprocity on an individual basis with the basic science boards of Alaska, Arizona, Connecticut, Michigan (grades must be 75% or more in each subject), Nevada, New Mexico, Oklahoma, South Dakota, and Texas.

Reciprocity on an individual basis with the medical licensing boards of California, Indiana, Kansas, Kentucky, New York *(subsequent to 1925—any before 1925 required to take examinations* in bacteriology and pathology), Oklahoma, Texas, Vermont, Virginia, Washington (grades must be 75% or more in each subject), and West Virginia.

Partial credit granted for grades in certain subjects passed in examinations of medical licensing boards of Alabama, Georgia, Louisiana, Maryland, North Carolina, Washington, and Wisconsin.

Nebraska

The board will permit waiver of [illegible] are considered individually. States [illegible] are those granting exemptions from [illegible] from Nebraska where the conditions of the laws and regulations have been met, even though these conditions differ somewhat from those of Nebraska. Waiver applied to both basic science boards and medical boards.

Nevada

Reciprocity on the basis of written examination with the basic science boards of Arizona, Colorado, Iowa, Minnesota, New Mexico, Oklahoma, Oregon, South Dakota, Tennessee, Texas, and Washington. Waiver with basic science boards of Arkansas, Florida, Michigan and Nebraska. Applicants holding a Wisconsin Basic Science certificate must be examined in bacteriology and chemistry.

New Mexico

By reciprocity with Arizona, Arkansas, Colorado, Iowa, Michigan, Minnesota, Nevada, Oklahoma, Oregon, Rhode Island, South Dakota, Tennessee, Washington, and Wisconsin. Certificates granted by waiver to doctors who have been in continuous practice for thirty consecutive years or more and who have taken and passed examinations in the basic sciences.

Oklahoma

Applicants are reviewed on an individual basis. If qualified, will be accepted provided other state extends a like privilege to those holding basic science certificate of Oklahoma Board. A basic science certificate is not a prerequisite for licensure by reciprocity but is a requirement for licensure by examination.

Oregon

Reciprocity with the basic science boards of Arizona, Arkansas, Colorado, Iowa, Michigan, Minnesota, Nebraska, Nevada, New Mexico, Oklahoma, South Dakota, Tennessee, Texas, Washington, and Wisconsin.

Rhode Island

Endorsement after oral examination with Massachusetts Board of Registration in Medicine and basic science boards of Colorado, District of Columbia, and Oklahoma.

South Dakota

Reciprocity with the basic science boards of Alaska, Arizona, Arkansas, Colorado, Iowa, Kansas, Michigan, Minnesota, Nebraska, Nevada, New Mexico, Oklahoma, Oregon, Rhode Island (on an individual basis), Tennessee, Texas, Washington, and Wisconsin.

Tennessee

Reciprocity with all basic science boards except Arkansas, Connecticut, Florida, Iowa, New Mexico, Rhode Island, and Wisconsin.

Texas

Reciprocity with the basic science boards of Alaska, Arizona, Arkansas, Colorado, Iowa, Michigan, Minnesota, Nebraska, Nevada, Oklahoma, Oregon, South Dakota, Tennessee, and Washington. Applicants from Wisconsin required to pass examination of Texas board in bacteriology, chemistry, and public health and hygiene.

Washington

Reciprocity with all basic science boards.

Wisconsin

Waiver to commissioned officers of the armed forces or the Public Health Service to an applicant who has passed part 1 of the examination of the National Board of Medical Examiners, to a physician licensed to practice medicine in a state not having a basic science law or licensed in a state before the establishment of a basic science board provided he has served an internship or has practiced for at least one year since the license was granted, to a physician licensed in Canada, and to foreign trained physicians holding an M.D. degree from an acceptable school who are licensed to practice medicine in the country in which the school attended is located. Reciprocity is also granted on the basis of written examination with all states having basic science boards.

that have been failed and the accumulation of credit. The variance which exists in the evaluation methods of the states makes it impossible to analyze the figures on a comparable basis from state to state.

Although it is recognized that the data presented may be useful to those seeking licensure in these states, it is advisable to supplement the information by direct communication with the basic science board. The present executive corresponding officer of each of the 22 basic science boards is as follows:

Alaska..........Dr. R. Harrison Leer, Room 204, Alaska Office Bldg., Juneau.
Arizona..........Mr. Herman E. Bateman, University of Arizona, Tucson.
Arkansas..........Mr. S. C. Dellinger, Zoology Department, University of Arkansas, Fayetteville.
Colorado..........Dr. Esther B. Starks, 1459 Ogden St., Denver 18.
Connecticut..........Mrs. Regina G. Brown, 258 Bradley St., New Haven 10.
District of Columbia...Mr. Paul Foley, 1740 Massachusetts Ave., N. W., Washington 6.
Florida..........Mr. M. W. Emmel, Box 340, Gainesville.
Iowa..........Mr. Elmer W. Hertel, Wartburg College, Waverly.
Kansas..........Dr. L. C. Heckert, Pittsburg State Teachers College, Lansing.
Michigan..........Mrs. Anne Baker, 116 Stevens T. Mason Bldg., W. Michigan Ave., Lansing 15.
Minnesota..........Dr. Raymond N. Bieter, 165 Millard Hall, University of Minnesota, Minneapolis.
Nebraska..........Mr. R. K. Kirkman, Room 1009, State Capitol Bldg., Lincoln 9.
Nevada..........Dr. Donald G. Cooney, Box 9005, University Station, Reno.
New Mexico..........Mrs. Marguerite Cantrell, Box 1522, Santa Fe.
Oklahoma..........Mrs. Lucille Haidek, 813 Braniff Bldg., Oklahoma City.
Oregon..........Dr. Earl M. Pallett, State Board of Higher Education, Box 5175, Eugene.
Rhode Island..........Mr. Thomas B. Casey, 366 State Office Bldg., Providence.
South Dakota..........Dr. Gregg M. Evans, 310 E. 15th St., Yankton.
Tennessee..........Dr. O. W. Hyman, 62 S. Dunlap St., Memphis.
Texas..........Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.
Washington..........Mr. Thomas A. Carter, Department of Licenses, Capitol Bldg., Olympia.
Wisconsin..........Mr. William H. Barber, 621 Ransom St., Ripon.

NATIONAL BOARD OF MEDICAL EXAMINERS

The National Board of Medical Examiners is a voluntary and unofficial examining agency, the purpose of which is to prepare and to administer qualifying examinations of such high quality that legal agencies governing the practice of medicine within each state may at their discretion grant successful candidates a license without further examination.

It is the function of the individual states to determine who shall practice within their borders and to maintain high standards of medical practice in

accordance with their own rules and regulations. In recognition of the thoroughness and widely accepted standards of the National Board examinations, its certificate is accepted as a suitable qualification for the practice of medicine by 46 licensing authorities in the states, the District of Columbia, and the territories of the United States. A number of the boards of examiners in the basic sciences accept the examination of the National Board of Medical Examiners in lieu of their own examination.

Michigan	10	Washington	10
Minnesota	25[2]	Wisconsin	10

Fee for registration without examination: [1] $25; [2] $50; [3] $20, nonresidents; $25 reciprocity; [4] $75, reciprocity; $12.50 reexamination per subject; [5] $50, reciprocity; $10 reexamination.

The examinations are divided into three separate parts. Examinations in parts 1 and 2 are held at approved medical centers in the United States and Canada. Part 3 is administered by examining boards in 37 centers throughout the United States.

The National Board admits to its examinations any student or graduate of an approved medical school in the United States or Canada. A candidate is eligible for part 1 who has completed the formal courses of the first two years in an approved medical school; eligibility for part 2 calls for completion of a four-year medical course in an approved medical school; a candidate is eligible for part 3 if he has passed parts 1 and 2, received a degree of doctor of medicine, and served at least one year in an approved hospital internship.

Although previously accepting graduates of certain foreign medical schools, the National Board does not, at the present time, admit to its examinations leading to certification any graduates of medical schools outside the United States and its territories and Canada.

Upon receipt of a request initiated by a state licensing board, a specialty board, or a medical school, an individual may be admitted to certain National Board examinations in order to satisfy special requirements or regulations of the licensing board, specialty board, or the medical school. In such cases the individual is not considered a can-

didate for National Board certification. He is admitted to the examinations as a service to the board or school initiating the request and the grades are, therefore, sent only to the board or school concerned.

An increasing number of medical schools are finding National Board examinations useful as an impartial evaluation of their students in comparison with students of other schools. A medical school may use the National Board examinations for an entire class of students when the school wishes to have an objective extramural test in individual subjects or as a comprehensive examination. Twenty-nine medical schools are using to some degree the services of the National Board of Medical Examiners. Medical schools may also request that a foreign medical student who is being considered for admission to advanced standing be permitted to take National Board examinations in order to determine the level of his medical knowledge.

The most notable addition to the services rendered by the National Board is the preparation and administration of the examinations of the Educational Council for Foreign Medical Graduates.

The written examinations of parts 1 and 2 all are of the objective, multiple-choice type and may be taken by students during the course of their training in the medical school. Each of the six examinations of part 1 and part 2 is developed by a separate committee which is appointed by the Board and consists of about six members, including department heads, teachers, and clinicians with recognized prominence in their own fields. These committees have wide geographic distribution. Part 3 is a clinical and practical examination of the candidate's ability in critical observation, in diagnostic acumen, and in the principles of therapy. The examination is divided into four periods allocated to the four major elements of general practice. In addition, essay type examinations are included in the clinical subjects of part 3.

Examinations in part 1 were held during 1958 in June and September and in part 2 in April and June. The part 3 examination is given in late June with a small limited interim examination in the late fall.

The tables that are presented refer to the results of examinations in all three parts since 1922, including the number who passed and failed examination and the number certified. This is the 37th annual compilation of these statistics. The board's first examination was given in October, 1916. From that date and up to and including a test given in June, 1921, 11 examinations were given and 268 candidates were certified. Since 1922 the examination has been divided into three parts.

Totals	38,686	37,836	850	2.2

Tables 42 and 43 record the results of examinations given in parts 1 and 2 during 1958 and for each year since 1922. The data shown in these tables represent examinations conducted rather than persons examined, and the figures thus include candidates who fail and are reexamined during the same year and those who may pass parts 1 and 2 in the same year. The examination in part 1, and occasionally in part 2, may be divided and taken at more than one examination period. Four or five subjects may be taken at one time and the remaining subjects of the part taken later. Candidates so examined during 1958 are listed in the tables under the heading of a column titled incomplete.

There were 4,210 examinations in part 1 given in 1958; 2,443 candidates passed, and 337, or 12.1%, failed. Incomplete examinations numbered 1,430. In part 2, 2,625 examinations were held, 2,540 passed, and 64, or 2.5%, failed. Fifteen incomplete examinations were given.

From 1922 to 1958, inclusive, a total of 82,725 examinations have been given in part 1 and 44,528 in part 2. In the 37-year period shown, there have been 7,678 failures in part 1 (13.2%), and 1,640 (3.7%) in part 2.

In 1958, 2,023 tests were given in part 3; 2,011 candidates passed and 12 (0.5%) failed. Results of examinations in part 3 in 1958 and in the 36 preceding years are given in table 44. In the 37-year period 38,686 were tested, of whom 37,836 were granted the certificate of the board. The percentage of failures in the board's final examination for this period was 2.2.

The 2,011 physicians certified as diplomates in 1956 represented 65 medical schools in the United States and Puerto Rico, one United States medical school no longer in operation, 9 in Canada, and *6 schools in other countries. The school and the* number of examinees from each are included in table 45.

In 1958, there were 3,215 licenses to practice medicine issued by endorsement of the certificate of the National Board of Medical Examiners in 43 states, the District of Columbia, Hawaii, and Puerto Rico. The number registered by each of these licensing boards is recorded in table 46. There have been 41,670 licenses issued on the basis of endorsement of the certificate of the National Board of Medical Examiners since 1915.

In 1958, there were 464 medical students who took part 1 and 889 who took part 2, not as candidates for National Board certification but only as a requirement of their own medical school. During the year, also, a total of 54 individuals who had two or more years of medical education in a foreign medical school and who were being considered for admission to a medical school in the United States were examined in either part 1 or part 2.

The National Board allows one reexamination in the event of failing a part. If a candidate fails for a second time, permission to take the examination for a third time is given only by special permission of the board and only if the candidate can demonstrate to the satisfaction of the board that there are special reasons justifying examination.

The corresponding officer of the National Board of Medical Examiners is Dr. John P. Hubbard, Executive Secretary and Treasurer. The address of the board is 133 S. 36th St., Philadelphia 4.

MEDICINE AND THE LAW

LIABILITY OF GOVERNMENTAL HOSPITALS FOR NEGLIGENCE

"The King can do no wrong!" This is the legal maxim which prevailed under English common law. The American common law adopted the principle of sovereign immunity, investing the state and federal governments with the royal privileges. Hence, state and federal governmental units have generally enjoyed a freedom from suits based upon negligence.

By statute, the sovereign immunity has been diminished in many instances, thus allowing certain kinds of suits against governmental agencies. Such action, of itself, does not necessarily make for liability unless the courts interpret these statutes, or other laws of the jurisdiction, as allowing governmental subdivisions to be liable for the negligence of their employees or agents.

The federal government hospitals remained immune from liability until the Federal Tort Claims Act waived the sovereign protection. Similarly, hospitals operated by states have retained their cloak of immunity unless the common law rule has been abrogated by statute.

Counties and municipalities do not fit so clearly into the traditional concepts of sovereign immunity. Most courts, however, have considered counties and cities to be instrumentalities created by the state legislatures and entitled to the benefits of the immunity of the parent body. This does not mean that city and county hospitals automatically enjoy the immunity which might apply, for example, to a fire department. In fact, some courts have distinguished the functions of a governmental unit created by a state and have determined that certain activities are governmental in nature, that is, are required for performance of the government's purposes, while other activities are proprietary, i. e., similar to or competitive with private business.

Whether operation of a hospital by a city or county is a governmental or a proprietary activity determines, in many jurisdictions, whether the hospital will enjoy immunity from liability for negligence. It is more of a legal conclusion than a factual finding, however, since the same activity may be considered governmental in one state and proprietary in another. This distinction constitutes the basis for the prevailing theory. There are numerous additional or subordinate theses, however. For instance:

In a few states the courts have concluded that if voluntary nonprofit hospitals enjoy charitable immunity, the governmental hospitals should also be immune from liability.

If a statute permits a governmental unit to operate a hospital but does not make this activity a mandatory one, a number of courts have held that the hospital, nevertheless, is clothed with sovereign immunity.

A few cases indicate that a county, as distinguished from a municipal corporation, is clearly performing a governmental function when it operates a hospital, and thus deserves to be free from liability.

Some courts felt so strongly about governmental immunity that they have supported it even upon a showing of gross negligence or wanton disregard for the safety of others.

Although the incorporation statute or its charter may allow a governmental unit to sue and be sued, courts have often held that this does not affect the immunity from liability for negligence enjoyed by governmental hospitals; the suit must be for some reason other than negligence, unless such immunity has been specifically waived.

If the corporate charter, or other legislative action by which the governmental hospital was authorized, enumerates the powers granted, and the injury complained of resulted from an activity not specifically authorized, most courts have held that the hospital continues to be immune; an act outside the apparent scope of authority does not customarily threaten liability for a governmental hospital.

Even if a governmental hospital acquires liability insurance as a precautionary measure, its immunity should not be affected, some courts hold.

In a number of states governmental hospitals have been held liable. The rationale of the courts has included these views:

If it is not mandatory for the governmental unit to operate a hospital, such activity is not considered governmental but rather is proprietary and governmental immunity is not applicable.

Receiving paying patients is inconsistent with a governmental function, hence there should be liability at least insofar as paying patients are concerned.

If voluntary nonprofit hospitals are liable in the state, governmental hospitals should be in no different position.

If the hospital has purchased liability insurance, immunity is waived at least to the extent of insurance coverage.

In the realm of voluntary nongovernmental hospitals, there is an unmistakable trend away from immunity and toward liability. Many states, through court decisions, have switched in the past few years. The courts in these states have decried charitable immunity as an anachronism out of step with contemporary concepts of justice. To a lesser extent, the courts have also been saying that governmental immunity in the hospital field is a harsh doctrine and should be set aside since the reasons for this rule also no longer exist; now that government is engaged in so many ventures which have not been included in its traditional functions, liability would be more appropriate.

The courts have not been in a position to reverse the immunity holdings relative to governmental hospitals as readily as with voluntary institutions, however. It is generally recognized that

---

This material was prepared by the Joint Committee on Professional Liability of the American Medical Association and the American Hospital Association.

legislative action is necessary to remove governmental immunity once the immunity has been established. This has been done in New York state via the Court of Claims Act, by the Federal Tort Claims Act for United States hospitals, and through interpretation of the Hospital Authority Act in Georgia.

There is a trend toward liability in governmental hospitals. Some recent court decisions in states which have considered the question for the first time indicate this, and further legislative action may be expected in other states. Insurance coverage to protect against this liability is generally available both for the hospital and for its employees (who, in any case, might be personally liable even if the hospital enjoys immunity).

CHART SHOWING TORT LIABILITY OF GOVERNMENTAL HOSPITALS TO PATIENTS

(Unless commented upon, it may be assumed that state owned institutions are immune from tort liability.)

ALABAMA

A public hospital corporation such as a county hospital, authorized by statute, performs a governmental function and is *immune* from liability to indigent or paying patients. *Garret v. Escambia County Hospital Bd.*, 94 So. 2d 762 (Ala., 1957).

ALASKA

Political subdivisions are *liable* for the negligence of their servants in operating hospitals to the same extent as private individuals, *Tuengel v. Sitka*, 118 F. Supp. 399 (D.C., Alaska, 1954), and possibly the state is liable as well under a special statute. Alaska Comp. Laws. Ann. §§ 56-7-1, 56-7-7 (Supp. 1958).

ARIZONA

A county hospital is engaged in a governmental function and is *immune* from negligence liability. *Lee v. Dunklee*, 326 P. 2d 1117 (Ariz., 1958).

ARKANSAS

No cases reported.

CALIFORNIA

County hospitals are *immune* from liability for "malpractice" injuries arising out of their operation, *Calkins v. Newton*, 36 Cal. App. 2d 262, 97 P. 2d 523 (1940); "District Hospitals" are likewise *immune* from liability, even to paying patients, *Talley v. Northern San Diego County Hospital District*, 41 Cal. 2d 33, 257 P. 2d 22 (1953). There is *liability*, however for dangerous or defective condition of county hospital property, *Burns v. American Casualty Co.*, 127 Cal. App. 2d 198, 273 P. 2d 605 (1954); and probably *liability* to paying patients in municipal hospitals, *Beard v. City and County of San Francisco*, 79 Cal. App. 2d 753, 180 P. 2d 744 (1947).

COLORADO

City and county hospitals are engaged in governmental activities and are thus *immune* from tort liability. *Schwalb v. Connely*, 116 Colo. 195, 179 P. 2d 667 (1947).

CONNECTICUT

No cases reported.

DELAWARE

No cases reported, but sovereign immunity is waived, by statute, if liability insurance exists. Del. Code Ann. Title 18 § 516 (Supp. 1958).

DISTRICT OF COLUMBIA

Federally owned hospitals would be *liable* within the provisions of the Federal Tort Claims Act. See discussion under "Federal" Hospitals owned by the District retain tort *immunity*. *Calomeris v. District of Columbia*, 125 F. Supp. 266 (D.C.D.C., 1954).

FLORIDA

A city is *liable* for negligent injuries received by a patient. *Goff v. Ft. Lauderdale*, 65 So. 2d 1 (Fla., 1953). County hospital is liable also. *Bourgeois v. Dade County*, 99 So. 2d 575 (Fla., 1957).

GEORGIA

A hospital organized under the Hospital Authority Act is *liable* for its torts. *Hall v. Hospital Authority of Floyd County*, 99 S.E. 2d 708 (Ga. App., 1957).

HAWAII

No reported cases. Federal hospitals would be *liable* within the provisions of the Federal Tort Claims Act. See discussion under "Federal."

IDAHO

Where a county is required by law to provide hospital care only for the indigent, there is *liability* to paying patients in a county hospital. *Henderson v. Twin Falls County*, 56 Idaho 124, 50 P. 2d 597 (1935). Also, by statute, state hospitals are liable to the extent of their insurance coverage. Id. Code §§ 41-3304, 3305 (Supp. 1957).

ILLINOIS

A government-owned hospital is devoted to public purposes and is *immune* from liability in absence of statutory provision to the contrary. *Olander v. Johnson*, 258 Ill. App. 89 (1930). A city-owned hospital is also *immune* either as a charity or because it promotes the public welfare under the general police powers. *Tollefson v. Ottawa*, 228 Ill. 134, 81 N.E. 823 (1907).

INDIANA

A city hospital performs a governmental function and is *immune* from tort liability. *Scott v. Indianapolis*, 75 Ind. App. 387, 130 N.E. 658 (1921).

IOWA

A county hospital is a proprietary function, at least insofar as paying patients are concerned; hence *liability* to paying patients. *Wittmer v. Letts*, 80 N.W. 2d 561 (Iowa, 1957).

KANSAS

Activities of a city hospital are proprietary and give rise to *liability* to a paying patient. *Stolp v. Arkansas City*, 180 Kan. 197, 303 P. 2d 123 (1956).

KENTUCKY

A city hospital performs a governmental function and is *immune* from liability for negligence. *Van Pelt v. Louisville*, 257 Ky. 256, 77 S.W. 2d 942 (1934). A Board of Claims hears claims against the state for negligent acts and may pay up to $10,000. Ky. Rev. Stat. Ann. § 44.070 (Supp. 1958).

LOUISIANA

Operation of a hospital by a governmental unit is a governmental activity and *immune* from tort liability. *Messina v. Societe Francaise De Bienfaissance*, 170 So. 801 (La. App., 1936). If a governmental hospital is covered by liability insurance, the insurer possibly may be liable to the amount of insurance.

MAINE

A hospital operated under legislative authority generally is *immune*, except for *liability* to paying patients. *Anderson v. Portland*, 130 Me. 214, 154 A. 572 (1931).

MARYLAND

Governmental *immunity* applies to governmental hospitals. *Thomas v. Board of County Commissioners*, 92 A. 2d 452 (Md. App., 1952). Whether a governmental hospital, if insured, is subject to tort liability to the extent of its coverage has not yet been determined. Ann. Code of Md., Art. 48A, § 85 (1957).

MASSACHUSETTS

A city hospital is *immune* from tort liability even if there has been gross negligence. *Young v. Worcester*, 253 Mass. 431, 149 N.E. 204 (1925).

MICHIGAN

City hospitals are *immune* as a governmental function. *Martinson v. Alpena*, 328 Mich. 595, 44 N.W. 2d 148 (1950); general charitable *immunity* also applies to government charitable functions such as a state university hospital. *Robinson v. Washtenaw Circuit Judge*, 228 Mich. 225, 199 N.W. 618 (1924).

MINNESOTA

A government agency is *liable* for negligence in its proprietary functions, which would include operation of a general hospital. *Swigerd v. Ortonville*, 75 N.W. 2d 217 (Minn., 1956); *Borwege v. Owatonna*, 190 Minn. 394, 251 N.W. 915 (1933).

MISSISSIPPI

Operation of a hospital by a governmental unit is considered a government function, hence *immunity* from tort liability. *Jones v. Amory*, 184 Miss. 161, 185 So. 237 (1939). No liability to paying patients, either. *Leland v. Leach*, 86 So. 2d 363 (Miss. 1956).

MISSOURI

Operation of a hospital is a proper function of government and brings *immunity*. *Schroeder v. City of St. Louis*, 360 Mo. 293, 228 S.W. 2d 677 (1950).

MONTANA

No cases reported.

NEBRASKA

No cases reported.

NEVADA

County hospital created under statute is not a legal entity and cannot be sued for negligence. *Bloom v. Southern Nevada Memorial Hospital*, 275 P. 2d 885 (Nev., 1954). Whether the county itself is responsible for hospital torts is not yet determined.

NEW HAMPSHIRE

Operation of a hospital by a city, under legislative authority, is considered a proprietary activity and is subject to tort *liability*. *Kardulas v. Dover*, 99 N.H. 359, 111 A. 2d 327 (1955).

NEW JERSEY

Immunity from liability for government hospitals, except that in cases of "active wrongdoing" or "positive misfeasance," as contrasted with ordinary negligence, there is liability. *Kress v. Newark*, 8 N.J. 562, 86 A. 2d 185 (1952).

NEW MEXICO

Operation of a governmental hospital is a governmental function; county hospital is *immune* from tort liability. *Elliott v. Lea County*, 58 N.W. 147, 267 P. 2d 131 (1954).

NEW YORK

Under Section 8, Court of Claims Act, the state waives its immunity. *Liability* of state, county, town, city and village hospitals is determined as if they were private individuals or corporations. *Becker v. City of New York*, 2 N.Y. 2d 226, 140 N.E. 2d 262 (1957). There is also *liability* of municipal corporations for the malpractice of doctors or dentists occurring in municipal hospitals if the professional services are rendered gratuitously in a charity case. Section 50-d, New York General Municipal Law (1956).

NORTH CAROLINA

Governmental *immunity* applies even to paying patients in a city-county hospital. *Hitchings v. Albemarle Hospital*, 220 F. 2d 716 (CA 4th, N.C., 1955). The state is liable up to $10,000, *under a special statute, for negligent acts. Gen.* Stat. of N. C. § 143-291 (1958).

NORTH DAKOTA

No cases reported.

OHIO

Municipally operated hospitals promote the public health, constitute a governmental function, and are *immune* from tort liability. *Lloyd v. Toledo*, 42 Ohio App. 36, 180 N.E. 716 (1931).

OKLAHOMA

A city hospital is a proprietary activity and is subject to tort *liability*. *Okmulgee v. Carlton*, 180 Okla. 605, 71 P. 2d 722 (1937).

OREGON

No cases reported.

PENNSYLVANIA

Immunity of governmental hospitals in Pennsylvania is a long standing rule of law. *Hand v. Philadelphia*, 8 Pa. Co. 213 (1890).

PUERTO RICO

The governmental nature of a public municipal hospital brings *immunity* from tort liability. *Villegas v. San Juan*, 19 P.R. 397 (1913).

RHODE ISLAND

No cases reported.

SOUTH CAROLINA

Governmental hospitals are *immune* from tort liability in absence of a statute to the contrary. *Mullins Hospital v. Squires*, 104 S.E. 2d 161 (S.C., 1958).

SOUTH DAKOTA

County functions, such as operating a hospital, are clothed with governmental *immunity*. *Jerauld County v. St. Paul-Mercury Indemnity Co.*, 71 N.W. 2d 571 (S.D., 1955).

TENNESSEE

Governmental hospitals derive an *immunity* from tort liability because they constitute a governmental function. *Lane v. Knoxville*, 170 Tenn. 482, 96 S.W. 2d 769 (1936). If covered by liability insurance, a municipal hospital waives immunity to the extent of coverage. *McMahon v. Baroness Erlanger Hospital*, 306 S.W. 2d 41 (Tenn. App., 1957).

UTAH

No cases reported.

VERMONT

No cases reported.

VIRGINIA

There is *immunity* from tort liability for governmental hospitals created under statutory authority. *Maia v. Eastern State Hospital*, 97 Va. 507, 34 S.E. 617 (1899).

WASHINGTON

By statute there is *immunity* for governmental hospitals from liability for the negligence of employees, agents, and officers. *Gile v. Kennewick, Public Hospital District*, 48 Wash. 2d 774, 296 P. 2d 662 (1956).

WEST VIRGINIA

A county hospital authorized by statute is a governmental activity and is *immune* from liability for negligence. *Shaffer v. Monongalia General Hospital*, 135 W. Va. 163, 62 S.E. 2d 795 (1950).

WISCONSIN

Governmental hospitals are *liable* for their proprietary functions. *Carlson v. Marinette County*, 264 Wis. 423, 59 N.W. 2d 486 (1953).

WYOMING

No cases reported.

FEDERAL

The Federal Tort Claims Act, 28 USC 2671 et. seq., provides for *liability* of the United States (except for interest prior to judgment and punitive damages) "in the same manner and to the same extent as a private individual under like circumstances." While the law of the place of injury usually governs, any governmental immunity in a state would be ignored since "private individuals" do not enjoy such immunity. Malpractice by a physician employed by the United States would be actionable against the United States. *Dishman v. U. S.*, 93 F. Supp. 567 (D.C. Md., 1950), except where the injured person is a serviceman treated as an "incident to the service." *Feres v. U. S.*, 340 U.S. 135 (1950).

FOREIGN

In England and Canada, where the general system of law is similar to that of the United States, a governmental body operating a hospital is liable for negligence just as a private individual or corporation would be under similar circumstances. *Cassidy v. Ministry of Health*, 2 K.B. 343 (1951) [Great Britain]; *Nyberg v. Provost Municipal Hospital Board*, Can. S.C.R. 226 (1927) [Canada].

This article is being published simultaneously in the June 1 issue of *Hospitals*.

MEDICAL NEWS

CALIFORNIA

Dr. Allen Named Department Head.—Dr. J. Garrott Allen, University of Chicago, was named to head the Stanford University Medical School's department of surgery. Dr. Allen will commence his new duties on July 1, just prior to the opening of the Medical School's new 22-million-dollar facilities nearing completion on the Palo Alto campus. He is professor of surgery and attending surgeon at the University of Chicago Clinics, where he has served continuously since 1938.

Dr. Whalman Honored.—Dr. Harold F. Whalman, chairman of ophthalmology at the College of Medical Evangelists, Los Angeles, will receive the Distinguished Nevadan Award during commencement ceremonies at the University of Nevada on June 1, "in recognition of [his] significant contribution to the scientific and social advancement of our nation." Dr. Whalman received his bachelor of arts degree from the University of Nevada in 1922. Since 1935, he has been a member of the faculty at the College of Medical Evangelists.

ILLINOIS

Mental Health Observance.—Governor William G. Stratton proclaimed the period April 26 to May 19 as "Eleventh Annual Mental Health Observance in Illinois." Governor Stratton's official proclamation urged "all citizens to join in the observance, visiting a state mental institution if possible, to the end that public awareness of the problem will stimulate the enlightened public action essential to a solution." More than 100 public and private agencies and organizations joined the Illinois Department of Public Welfare as co-sponsors of the statewide observance. The 11th annual Mental Health Dinner was held in Springfield May 19, featuring Dr. Robert H. Felix, director, National Institute for Mental Health, as guest speaker.

Chicago

Meeting of Rush Alumni.—The Alumni Association of Rush Medical College will hold a meeting June 9, 12:30 p. m., at the Shelburne Hotel, Atlantic City, N. J., under the presidency of Dr. Lowell D. Snorf, Chicago. For information, write Dr. James W. Merricks, Secretary, Alumni Association of Rush Medical College, 1758 W. Harrison St., Chicago 12. Luncheon fee is $5.

Personal.—Dr. John A. D. Cooper, professor of biochemistry, was named associate dean of Northwestern University Medical School. Since 1956, Dr. Cooper has been assistant dean. Dr. Cooper organized a course on the application of nuclear physics in biology and medicine which he first taught in 1949, reportedly the first of its kind offered in medical schools.——John H. Rust, D.V.M., project director, department of food technology, Massachusetts Institute of Technology, Cambridge, was made head of the newly established Section on Nuclear Medicine at the University of Chicago's School of Medicine.

MASSACHUSETTS

Annual Lecture.—Dr. James H. Means, Jackson Professor of Clinical Medicine, Emeritus, at Harvard and former chief of medical services at the Massachusetts General Hospital, delivered the annual Gay Lecture on Medical Ethics at the Harvard Medical School, Boston, on "Profession or Business" May 13. The Gay Lectures were established at Harvard in 1917 by Dr. George W. Gay, a graduate of Harvard Medical School.

Medical Center Established.—Formation of a Boston University–Massachusetts Memorial Hospitals Medical Center, to continue and enlarge "the cooperative enterprises of the two institutions in the advancement of patient care, of education in medicine and other health services, and of research," was announced May 2 by President Harold C. Case, of Boston University. The move converts to a formal association the informal cooperation which has existed over a period of years between the Boston University School of Medicine and its principal teaching hospital, the Massachusetts Memorial, located in Boston's South End. The Medical Center will be governed by a joint administrative board, composed of the presidents and three representatives each from the trustees of the university and the hospitals and a member-at-large elected by the other eight. The board will have over-all supervision of the Medical Center, including medical education, medical care, research, and any other training programs conducted by any unit of the center. A full-time director of the medical center, who will serve as chief executive officer of the board and the center, will be appointed. The cost of establishing the center and paying for the services of the director and the expenses of his office will be shared equally by the university and the hospitals, President Case said. The offices of dean of the School of Medicine

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

and administrator of the hospitals will continue, and final authority for the program of each institution will remain with its respective board of trustees.

MINNESOTA

Dr. Pruitt Goes to Texas.—Dr. Raymond D. Pruitt, a consultant in internal medicine in the Mayo Clinic since 1943, associate director of the Mayo Foundation from 1954 to 1956, and professor of medicine in the Mayo Foundation, Graduate School, University of Minnesota, will leave that institution on July 1 to become chairman, department of medicine, Baylor University College of Medicine, Houston, Texas. The appointment includes assignment as physician-in-chief to the Jefferson Davis Hospital and chief consultant in medicine to the Veterans Administration Hospital, Houston.

MONTANA

New President.—Dr. Thaddeus L. Lockridge, Whitefish, succeeded to the office of president of the Flathead County Medical Society and will complete the unexpired term of Dr. Kenneth J. Lampert, who is moving to New Mexico to join the staff of the New Mexico Hospital for Retarded Children.

Society News.—The annual meeting of the Montana Society of Pathologists was held Feb. 7, 1959, in Butte. Newly elected officers for the present year are: president, Dr. Ernst J. Eichwald, of the Montana Deaconess Hospital, Great Falls, and secretary-treasurer, Dr. John P. Pfaff, of Columbus Hospital, Great Falls.

Rehabilitation Meeting.—The 1959 annual meeting of the Montana Association for Rehabilitation, under the presidency of Dr. Jesse T. Schwidde, will be held in Billings, June 17-18, at Marillac Hall. The theme will be "Rehabilitation in Action," and the program will include progress reports from various areas and agencies in the state as well as the annual business meeting. The scientific program will include clinical evaluation demonstrations, pediatric rehabilitation problems, geriatrics, and a discussion of osteoarthritis and paraplegic cases. Dr. Howard A. Rusk, chairman, department of physical medicine and rehabilitation, New York University–Bellevue Medical Center, and Dr. Ross T. McIntyre, executive director, International College of Surgeons, will participate. Also included on the program will be a tour of the new rehabilitation unit of St. Vincent's Hospital, Billings. On Thursday evening, June 18, the association will hold its annual banquet at the Northern Hotel at 7:30 p. m.

NEW HAMPSHIRE

Dr. Lobitz Goes to Oregon.—Dr. Walter C. Lobitz Jr., professor of dermatology, Dartmouth Medical School, and chief of the department of dermatology at Hitchcock Clinic in Hanover, was named professor and head of the division of dermatology at the University of Oregon Medical School, Portland, effective July 1. He succeeds Dr. Thomas B. Fitzpatrick, who accepted a similar position at Harvard University Medical School, Boston. Dr. Lobitz was a fellow in dermatology and syphilology at the Mayo Foundation from 1942 to 1945 and became a diplomate of the American Board of Dermatology in 1947.

OHIO

State Medical Election.—Dr. Frank H. Mayfield, Cincinnati neurosurgeon, was installed as president of the 113-year-old Ohio State Medical Association April 23, and Dr. Edwin H. Artman, Chillicothe general practitioner, was selected as president-elect. Dr. Artman will be installed as president at the 1960 annual meeting in Cleveland. Retiring president was Dr. George A. Woodhouse, Pleasant Hill general practitioner. Elected to serve on the Council are Dr. Ray M. Turner, Springfield; Dr. Wendell Green, Toledo; Dr. Robert E. Tschantz, Canton; Dr. Robert M. Inglis, Columbus; and Dr. William D. Monger, Lancaster (reelected).

TEXAS

Foundation for Research in Psychiatry.—Plans for newly formed Timberlawn Foundation for Education and Research in Psychiatry were set up by the board of trustees at their regular meeting in Dallas. These include proposed invitations to leading psychiatrists and scientists to teach and do research at Timberlawn and give public lectures. Besides the stepped-up training of residents in psychiatry, of externs and interns, of therapists and nurses at Timberlawn, several areas of research already underway will be continued, including a review of 12,000 cases of mental illness treated at Timberlawn since 1917, clinical research on schizophrenic ability to handle abstract concepts, research on an attempt to predict the therapeutic results in schizophrenics, and research on the husbands of schizophrenic wives. Psychiatric counseling of business executives and religious leaders will be expanded. Long-range plans include an endowment fund of $1,500,000, three buildings to allow expansion of research and education program, and a memorial lectureship under which "eminent psychiatrists" will be invited to work with the foundation for a full year. Timberlawn Foundation is a nonprofit organization formed last year by a group of Dallas business and professional men to carry on and expand the research and education program which has been carried on at Timberlawn Sanitarium for many years. Specific aims of the foundation are to promote psychiatry and its related sciences, to give scientists an opportunity to do research, and to train physicians, nurses, and therapists in mental illness.

WYOMING

Annual Meeting in Moran.—The 56th annual meeting of the Wyoming State Medical Association will be held at Jackson Lake Lodge, Moran, June 11-13, under the presidency of Dr. L. Harmon Wilmoth, Lander. The House of Delegates will convene the morning of June 12. Two movies are scheduled, "Open-Heart Surgery Using the Kay–Anderson Heart–Lung Machine," by Dr. Jerome H. Kay, Beverly Hills, Calif., and "Cold Coning of the Uterine Cervix," by Dr. Harry W. Seiger, Santa Monica, Calif. Participants include the following: Drs. Ralph C. Benson, Portland, Ore.; Ralph M. Stuck, Denver; Edward H. Rynearson, Rochester, Minn.; H. Mason Morfit, Denver; John M. Salyer, Denver; Charles H. Scheifley, Rochester, Minn.; Alan R. Mortiz, Cleveland; and Edgar J. Poth, Galveston, Texas. Registration fee is $25, with medical students admitted free. For information, write Mr. Arthur R. Abbey, Box 2036, Cheyenne, Wyo., Executive Secretary.

GENERAL

National Recreation Month.—The National Recreation Association announced that June has been proclaimed National Recreation Month with the theme "Find New Worlds Through Recreation." The four weeks of the month, "designed to show the value and scope of leisure time activities," are Youth Fitness Week, Family Recreation Week, Arts and Recreation Week, and Service-Through-Recreation Week. Recreation Month materials are available from the National Recreation Association by writing the Public Information and Education Department, 8 W. Eighth St., New York 11.

Gastroenterology Meeting in Atlantic City.—The eighth meeting of the Gastroenterology Research Group will be held in Trimble Hall, Claridge Hotel, Atlantic City, the afternoon of June 4. The meeting will be a symposium on "Fine Structure as Related to Absorption, Synthesis and Transport in the Gastrointestinal Tract." The program has been arranged by Dr. Wade Volwiler, Seattle and Dr. Albert I. Mendeloff, Baltimore, and will be moderated by Dr. H. Stanley Bennett, Seattle. An informal dinner will follow the afternoon meeting. The group, in cooperation with the American Gastroenterological Association, will sponsor a morning program, the Gastroenterological Research Forum, which will consist of a series of 10-minute papers.

Meeting on Diabetes.—The 19th annual meeting of the American Diabetes Association will be held June 6-7 at the Chalfonte–Haddon Hall, Atlantic City, N. J., under the presidency of Dr. Alexander Marble, Boston. A total of 24 papers are scheduled for presentation in addition to 16 papers to be read by title. At the banquet June 6, 7:30 p. m., following an address by Dr. Marble, awards will be presented as follows: the Lilly Award to Dr. Marvin D. Siperstein, Dallas; a Banting Medal to Dr. George W. Thorn, Boston; a Banting Medal to Dr. E. T. Bell, Minneapolis. Dr. Boland Hughes, Philadelphia, will present "The Contemporary Scene in the U. S. S. R." at the banquet. A panel discussion on "Oral Hypoglycemic Agents" will be moderated by Dr. Garfield G. Duncan, Philadelphia, on the afternoon of June 7.

Geriatric Meeting in Atlantic City.—The 16th annual meeting of the American Geriatrics Society will be held June 4-5 at the Hotel Traymore, Atlantic City, N. J., under the presidency of Dr. Warren H. Cole, Chicago. Ten papers are scheduled for presentation, and the following panel discussions and moderators are planned:

Problems of the Aged in Industry, Dr. George C. Dowd, Worcester, Mass.
Concepts of the Medical Profession in Relation to Aging, Dr. Joseph D. McCarthy, Omaha.
Surgery in the Aged, Dr. Frank Glenn, New York City.
Advances in the Diagnosis and Treatment of Cerebrovascular Disease, Dr. Irving S. Wright, New York City.

The annual reception and dinner will be held June 4, 6:30 p. m. For information, write Dr. Richard J. Kraemer, 2907 Post Rd., Warwick, R. I., Secretary-Treasurer.

Meeting of Gastroscopic Society.—The 18th annual meeting of the American Gastroscopic Society will be held June 7 in Haddon Hall, Atlantic City, N. J. The program includes the following symposiums and moderators:

Gastroscopic Color Photography, Dr. Frank B. McGlone, Denver.
Endoscopic Biopsy of the Stomach, Dr. C. Wilmer Wirts, Philadelphia.
Instruments and Techniques for Esophagoscopy, Dr. Herman J. Moersch, Rochester, Minn.

The annual banquet at 7:30 p. m. will conclude the meeting, with Capt. Finn Ronne presenting "Exploring Antarctica." Dr. J. Edward Berk, Detroit, president of the society, will preside at the banquet. For information, write Dr. Arthur M. Olsen, 200 First St., S. W., Rochester, Minnesota, Secretary-Treasurer.

Italian Psychiatrist Receives Travel Award.—In ceremonies held during the annual convention of the American Psychiatric Association meeting, Dr. Ugo Cerletti, professor of neuropathology and psychiatry, University of Rome, was made a Laureate of the Purdue Frederick Medical Achievement Travel Award. Dr. Cerletti was cited for his "long and outstanding record of important research contributions in the science of psychiatry." The award winner is known for the introduction of electric convulsive treatment in psychiatric therapy. The Medical Achievement Travel Award is sponsored by The Purdue Frederick Company of New York and is administered by the International Council for Health and Travel. The award enables recipients to attend and participate in medical and scientific meetings here and abroad to "further the international exchange of scientific and medical research on a physician-to-physician basis."

Society News.—The American Academy for Cerebral Palsy officers for this year are as follows: Drs. Alvin J. Ingram, Memphis, Tenn., president; Raymond R. Rembolt, Iowa City, president-elect; Temple S. Fay, Philadelphia, vice-president; Glidden L. Brooks, Providence, R. I., secretary; and Samuel B. Thompson, Little Rock, Ark., treasurer. The 1959 annual meeting will be held in Los Angeles Nov. 30-Dec. 2 at the Hotel Statler.——At the 12th annual meeting of the **Neurosurgical Society of America**, the following officers were elected: president, Dr. Collin S. MacCarty, Rochester, Minn.; vice-presidents, Drs. Edward B. Schlesinger, New York City, and Thomas J. Holbrook, Huntington, W. Va.; secretary, Dr. Raymond K. Thompson, Baltimore; and treasurer, Dr. Bertram Selverstone, Boston. The next meeting of the society will be held at Del Monte Lodge, Calif., March 30-April 2, 1960.——As of April 24, the new address of the **American Foundation for Tropical Medicine, Inc.**, will be Room 715, 551 Fifth Ave., New York 17; Telephone: MUrray Hill 7-7290.

Conference on Angiology.—As part of the 10th anniversary observance of the founding of the Angiology Research Foundation, a World Conference of Angiology will be held in Atlantic City, N. J., June 5-7, in connection with the fifth annual meeting of the American College of Angiology. Dr. David B. Allman, past-president, American Medical Association, and Brig. Gen. Thomas W. Mattingly, director of medical education, Washington Hospital Center, Washington, D. C., are the honorary co-chairmen of the conference. The cochairmen are Alfred Halpern, Ph.D., president, Angiology Research Foundation, Dr. Paul S. Lowenstein, president, American College of Angiology, and Dr. Saul S. Samuels, editor-in-chief of *Angiology*. Forty-one scientific papers are to be presented by a total of 37 researchers from 10 different countries, including Argentina, Canada, six countries of Europe, and many parts of the United States. Dr. Charles W. Mayo, head of a section on surgery, Mayo Clinic, Rochester, Minn., and chief United States delegate to the World Health Assembly of the United Nations, will be the principal speaker at a reception and banquet Saturday, June 6. The World Conference of Angiology, sponsored by the Angiology Research Foundation, the American College of Angiology and by *Angiology*, is being supported by educational grants from Mead Johnson & Company and the Ortho Research Foundation. All sessions are to be held at the Marlborough-Blenheim Hotel and will be open to all members of the medical profession.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

CANADA

Summer School Guest Speakers.—The Vancouver Medical Association Summer School to be conducted June 1-5 at the Stanley Park Pavilion, Vancouver, B. C., will have the following guest speakers:

Dr. Lennox G. Bell, dean, Faculty of Medicine, University of Manitoba; Prof. Hugh McLaren, department of obstetrics and gynaecology, Queen Elizabeth Hospital, Birmingham, England; Dr. George T. Pack, associate professor of clinical surgery, Cornell University School of Medicine, New York City; Dr. Donald R. Smith, clinical professor of urology, University of California School of Medicine, Berkeley-San Francisco; and Dr. Theodore E. Walsh, professor of otolaryngology, Washington University, St. Louis.

CORRECTION

Hyperthyroidism in Infants at Birth.—In the initial answer to the Question and Answer with this title (Feb. 7, page 656) the consultant prepared a section on the mercaptoimidazoles as well as a separate section on the iodinated goitrogens such as iothiouracil sodium. Because of the limitation of space, our consultant was asked to shorten his answer. In the shortening procedure, the drug referring to the first group was left in as an example of the second.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Various Centers: Parts I and II, June 16-17; Part I only, Sept. 9-10. Examinations must be received at least six weeks in advance of a specific examination date. Examining centers established after close of registration. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates: Stations around the world, Sept. 22. Final date for filing applications is June 22. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Written.* Montgomery, June 16-18. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery 4.

Alaska:* On application in Anchorage or Fairbanks. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Arizona:* *Reciprocity.* Phoenix, July 15-17. Exec. Sec., Mr. Robert Carpenter, 826 Security Bldg., Phoenix.

Arkansas:* *Examination and Reciprocity.* Little Rock, June 11-12. Sec., Dr. Joe Verser, Harrisburg.

California: *Written.* San Francisco, June 15-18; Los Angeles, Aug. 17-20; Sacramento, October 19-22. *Oral.* San Francisco, June 13; Los Angeles, August 15; San Francisco, November 14. *Oral and Clinical.* San Francisco, June 14; Los Angeles, August 16; San Francisco, Nov. 15. Sec., Dr. Louis E. Jones, Room 536, 1020 N Street, Sacramento.

Colorado:* *Examination.* Denver, June 9-10. *Reciprocity.* Denver, July 14. Sec., Dr. John B. Farley, 712 Republic Bldg., Denver 2.

Connecticut:* *Homeopathic Board. Reciprocity.* Derby, June 9. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby. *Regular Board. Examination.* Hartford, July 14-16. Sec., Dr. Staley B. Weld, 160 St. Ronan St., New Haven.

Delaware: *Examination.* Dover, July 14-16. *Endorsement.* Dover, July 23. Sec., Dr. Joseph S. McDaniel, Professional Bldg., Dover.

District of Columbia:* *Written.* Washington, June 8-9. Final date for filing application is May 1. Mr. Paul Foley, Deputy Director, 1740 Massachusetts Ave., N. W., Washington.

Florida:* *Examination.* Miami Beach, June 21-23. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Georgia: *Examination and Reciprocity.* Atlanta, June 10-11. Sec., Mr. C. L. Clifton, 224 State Capitol, Atlanta 3.

Guam: *Subject to Call.* Act. Sec., Dr. F. L. Conklin, Agana.

Hawaii: *Written.* Honolulu, July 13-14. Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Idaho: *Examination and Endorsement.* Boise, July 13. Exec. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination.* Chicago, July 7-10. *Reciprocity.* Chicago, July 10. Supt. of Registration, Mr. Frederic B. Selcke, Capitol Building, Springfield.

Indiana: *Examination.* Indianapolis, June 17-19. Exec. Sec., Miss Ruth V. Kirk, 538 K. of P. Bldg., Indianapolis.

Iowa:* *Examination.* Iowa City, June 15-17. Exec. Sec., Mr. Ronald V. Saf, State Office Bldg., Des Moines 19.

Kansas:* *Examination and Endorsement.* Kansas City, June. Sec., Dr. F. J. Nash, New Brotherhood Bldg., Kansas City.

Kentucky: *Examination.* Louisville, June 8-10. Sec., Dr. Russell E. Teague, 620 South Third St., Louisville 2.

Louisiana: *Examination. and Reciprocity.* New Orleans, June 4-6. Sec., Dr. Edwin H. Lawson, 930 Hibernia Bank Bldg., New Orleans.

Maine: *Examination and Reciprocity.* Augusta, July 14-16. Sec., Dr. Stephen A. Cobb, Sanford.

Maryland: *Examination.* Baltimore, June 10-13. Sec., Dr. Frank K. Morris, 1211 Cathedral St., Baltimore 1.

Michigan:* *Examination.* Ann Arbor and Detroit, June 8-10. Sec., Dr. E. C. Swanson, 118 Stevens T. Mason Bldg., West Michigan Ave., Lansing 8.

Mississippi: *Examination and Reciprocity.* Jackson, June 22-24. Sec., Dr. A. L. Gray, Old Capitol, Jackson 13.

Missouri: *Examination.* St. Louis, May 29-30. Exac. Sec., Mr. John A. Hailey, Box 4, State Capitol Bldg., Jefferson City.

Montana: *Examination and Reciprocity.* Helena, Oct. 6. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

Nebraska:* *Examination.* Omaha, June 15-17. Director, Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

Nevada: *Examination and Reciprocity.* Reno, June 2. Sec., Dr. George H. Ross, 112 North Curry St., Carson City.

New Hampshire: *Examination and Reciprocity.* Concord, Sept. 9-12. Sec., Dr. Edward W. Colby, 107 State House, Concord.

New Jersey: *Examination.* Trenton, June 16-18. Sec., Dr. Royal A. Schaaf, 28 West State St., Trenton 8.

New York: *Examination.* New York, Rochester, Syracuse, Buffalo and Albany, June 23-26. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

North Carolina: *Written. Examination and Endorsement.* Raleigh, June 15-18. Sec., Dr. Joseph J. Combs, 716 Professional Bldg., Raleigh.

North Dakota: *Examination and Reciprocity.* Grand Forks, July 8-11. Sec., Dr. C. J. Glaspel, Box 228, Grafton.

Ohio: *Examination.* Columbus, June 18-20. Sec., Dr. H. M. Platter, 21 West Broad St., Columbus 15.

Oklahoma:* *Examination.* Oklahoma City, June 2-3. Exec. Sec., Mrs. E. L. Haidek, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Examination.* Portland, July 7-9. *Reciprocity and Endorsement.* Portland, July 9-11. Exec. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Pennsylvania: *Examination and Endorsement.* Philadelphia and Pittsburgh, July 1-3. Sec., Mrs. Margaret G. Steiner, Box 911 Harrisburg.

GOVERNMENT SERVICES

NAVY

Personal.—Capt. Lynn S. Beals Jr., M. C., United States Navy, was placed on the retired list on April 1, after completing more than 20 years of active naval service.——Rear Adm. Irwin L. V. Norman, M. C., U. S. Navy, was placed on the retired list of officers of the U. S. Navy on May 1. He had served in the Bureau of Medicine and Surgery, Navy Department, since February, 1955; he has been Assistant Chief of the Bureau for Personnel and Professional Operations and Inspector General of Medical Department Activities, taking over the latter duties in March, 1958. On retiring he had more than 31 years of active naval service.

VETERANS ADMINISTRATION

Research in Aging.—A forward look at medical research of the future to prolong health and happiness for the aging population is available in a booklet entitled "VA Prospectus, Research in Aging," a compilation of material from a meeting of the VA Advisory Committee on Problems of Aging, distinguished guests, and VA Department of Medicine and Surgery staff members. The book is divided into five presentations, each followed by discussion: (1) Aging of Molecules—Aging and Ground Substance of Connective Tissue, by Isidore Gersh, Ph.D., Department of Anatomy, University of Chicago School of Medicine, (2) Aging of Cells, by Robert J. Boucek, M.D., Department of Cardiovascular Disease, University of Miami School of Medicine, (3) Aging of Organs—Aging and the Nervous System, by James E. Birren, M.D., chief of the Section on Aging of the National Institute of Mental Health, (4) Aging of Individuals—Some Fundamental Aspects of the Aging Process, by Charles F. Geschickter, M.D., Department of Pathology, Georgetown University School of Medicine, and (5) Aging of Groups, by Jack Weinberg, M.D., attending psychiatrist at Michael Reese Hospital, Chicago. A summary of the conference, by Wilburt C. Davison, M.D., dean of the Duke University School of Medicine, is also included.

Athol Gordon, M.D., William S. Middleton, M.D., John B. Barnwell, M.D., Martin M. Cummings, M.D., Charles C. Chapple, M.D., Joseph Bernsohn, Ph.D., Lee D. Cady, M.D., Neal W. Coppinger, Ph.D., Charles E. Hogancamp, M.D., Kung-Ying Tang Kao, M.D., Ph.D., Thomas H. McGavack, M.D., Stewart G. Tuttle, M.D., John A. Ward, M.D., and others also participated. Dr. Charles C. Chapple is the editor. Copies are available from the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C., at a price of $1.50 each.

PUBLIC HEALTH SERVICE

Air Pollution.—The complete proceedings of the National Conference on Air Pollution which was held in Washington in November have been published in book form. The 526-page volume includes the full texts of all the talks plus reports of discussions. The report covers the entire air pollution field—extent, sources, health effects, economic and social effects, control methods, and administrative aspects. It is identified as Public Health Service Publication 654 and is available at $1.75 from the Superintendent of Public Documents, U. S. Government Printing Office, Washington 25, D. C.

FOOD AND DRUG ADMINISTRATION

Color Used in Lipstick.—Seventeen coal-tar colors would be removed from the approved list for unrestricted use in drugs and cosmetics under a proposed order because they cannot be certified as harmless for use in products which in normal use may enter the digestive system. Under the proposed action, these colors could not be used in lipsticks, and the variety of shades now available would be decreased appreciably until cosmetic manufacturers find new ways of reproducing these shades. Seven of these 17 colors caused definite injury to laboratory animals when fed in amounts making up 0.25 to 2.0% of the diet. The other 10 are closely related in their chemical structure to these seven.

There have as yet been no reports of injury to users of lipstick, drugs, or foods made with these coal-tar derivatives. Although the amounts of these colors that get into the digestive system are smaller than those used in Food and Drug Administration (FDA) tests, under the law as interpreted by the Supreme Court the FDA cannot set the amounts of coal-tar colors to be used in foods, drugs, and cosmetics and, accordingly, cannot certify to the safety of colors for unrestricted use unless they are completely harmless. The FDA will not only stop certifying new batches for internal use, but will also stop the use of any stock outstanding. Interested persons are allowed 30 days after publication of these proposals in the federal register to make written comments. These comments will be taken into account by the commissioner of food and drugs in the drafting of an order.

DEATHS

Areson, William Henry Ⓜ De Soto City, Fla.; Columbia University College of Physicians and Surgeons, New York City, 1896; veteran of World War I; fellow of the American College of Surgeons; formerly practiced in Upper Montclair, N. J., and served as president of the Essex County Medical Society; for many years director of board of health of Montclair, N. J., where he was president of the staff of the Mountainside Hospital; died in Arcadia March 7, aged 84.

Arrasmith, Thomas Milton Jr. Ⓜ Richmond, Va.; Jefferson Medical College of Philadelphia, 1924; retired from the regular U. S. Navy on June 30, 1956; veteran of World War II; chief of the bureau of medical aid of the city department of public health; died in St. Luke's Hospital March 5, aged 59.

Barksdale, George Edward Ⓜ Fletcher, N. C.; University College of Medicine, Richmond, 1899; veteran of World War I; died March 6, aged 89.

Becker, Israel Ⓜ Chicago; Dalhousie University Faculty of Medicine, Montreal, Que., Canada, 1927; served on the faculty of the Chicago Medical School; on the staffs of the Franklin Boulevard Hospital, Mount Sinai Hospital, and the Louis A. Weiss Memorial Hospital, where he died March 10, aged 59.

Blackford, Harry Ⓜ Seattle; University of Oregon Medical School, Portland, 1914; veteran of World War I; died in the Swedish Hospital Feb. 23, aged 74.

Boor, Seymour Carl, Creston, Ohio; University of Wooster Medical Department, Cleveland, 1898; served on the staff of the Wooster (Ohio) Community Hospital; died Feb. 16, aged 90.

Cook, Robert Milton, Boones Mill, Va.; Medical College of Virginia, Richmond, 1954; on the staff of the Franklin Memorial Hospital in Rockymount; died in Roanoke Feb. 27, aged 32.

Couche, James Buxton, San Diego, Calif.; University of Toronto Faculty of Medicine, Toronto, Ontario, Canada, 1899; veteran of World War I; died in the Scripps Metabolic Clinic in La Jolla Feb. 16, aged 88.

Cummings, Damon Ward Ⓜ Kansas City, Mo.; University of Louisville (Ky.) School of Medicine, 1928; veteran of World War II; on the staff of the Veterans Administration Hospital; died Feb. 28, aged 59.

Drake, Arthur Knowlton Ⓜ Toulon, Ill.; Harvard Medical School, Boston, 1898; served as superintendent of the Elmgrove Sanatorium in Bushnell; at one time associated with the State Infirmary in Tewksbury, Mass.; died in the Methodist Hospital in Peoria, Feb. 20, aged 86.

Edison, Earl Maynard Ⓜ San Marino, Calif.; Northwestern University Medical School, Chicago, 1937; member of the American Academy of General Practice; veteran of World War II; died Feb. 20, aged 49.

Eells, Joseph Oliver, West Palm Beach, Fla.; Tufts College Medical School, Boston, 1901; died Feb. 25, aged 82.

Ellerbrook, George Edward, Vevay, Ind.; University of Louisville (Ky.) School of Medicine, 1932; coroner of Switzerland County; on the staff of the King's Daughters' Hospital in Madison; died Feb. 25, aged 51.

Ellyson, Charles Wright Ⓜ Waterloo, Iowa; State University of Iowa College of Medicine, Iowa City, 1905; fellow of the American College of Surgeons and the International College of Surgeons; served as president of the Waterloo Medical Society; treasurer of the Black Hawk County Medical Society from 1920 to 1929; for 10 years councilor of the Sixth District of the Iowa State Medical Society; associated with the Allen Memorial, Schoitz Memorial, and St. Francis hospitals; died March 1, aged 81, of coronary occlusion.

Fatherree, John Pleasant Ⓜ Laurel, Miss.; Tulane University School of Medicine, New Orleans, 1939; member of the Southeastern Surgical Congress; fellow of the International College of Surgeons and the American College of Surgeons; medical director and superintendent of the South Mississippi Charity Hospital; on the staff of the Jones County Community Hospital; died Feb. 22, aged 51.

Finch, Frederic Arlington, Amagansett, N. Y.; Baltimore University School of Medicine, 1899; retired coroner of Suffolk County; on the staff of the Southampton (N. Y.) Hospital; died Feb. 12, aged 82.

Fredrickson, Gereon Ⓜ Iron Mountain, Mich.; Chicago College of Medicine and Surgery, 1917; veteran of World War I; served as mayor of Iron Mountain; member of the board of education; physician for Iron Mountain schools and served as director of the Dickinson County Health Department; died in the Veterans Administration Hospital Feb. 22, aged 64.

Ⓜ Indicates Member of the American Medical Association.

Goldstein, Leon Aaron Ⓜ Syracuse, N. Y.; Syracuse University College of Medicine, 1928; member of the American Academy of General Practice; veteran of World War II; on the staff of the Crouse-Irving Hospital; died in St. Petersburg, Fla., Feb. 18, aged 55.

Gormley, John Harry Ⓜ Winnetka, Ill.; Northwestern University Medical School, Chicago, 1927; died March 12, aged 58.

Gould, George Richard Ⓜ Conrad, Iowa; State University of Iowa College of Medicine, Iowa City, 1916; past-member of the school board; veteran of World War I; for eight years member of the hospital board, Grundy County Memorial Hospital in Grundy Center, where he died Feb. 18, aged 72.

Havens, Frederick Morgan Ⓜ Niagara Falls, N. Y.; University of Buffalo School of Medicine, 1933; member of the American Society of Anesthesiologists; served a residency in anesthesia at Bellevue Hospital in New York City; veteran of World War II; on the staffs of the Memorial and St. Mary's hospitals; died Feb. 27, aged 49.

Hennings, Albert Ernest Ⓜ Tuttle, Okla.; St. Louis College of Physicians and Surgeons, 1907; died in the Wesley Hospital, Oklahoma City, Feb. 28, aged 80.

Horkins, Harold Albert Ⓜ Detroit; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1928; certified by the National Board of Medical Examiners; associated with St. Mary's and Holy Cross hospitals; died Jan. 11, aged 56.

Jeans, Howard Stafford Ⓜ Lynwood, Calif.; George Washington University School of Medicine, Washington, D. C., 1943; member of the American Academy of General Practice; veteran of World War II; on the staff of St. Francis Hospital, where he died Feb. 25, aged 41.

Johnston, Crowell William Ⓜ West Palm Beach, Fla.; University of Georgia Medical Department, Augusta, 1899; died Feb. 24, aged 83.

Keating, *Peter McCall*, *Philadelphia; born in* Atlantic City, N. J., July 21, 1884; University of Pennsylvania Department of Medicine, Philadelphia, 1910; served on the faculty of his alma mater; specialist certified by the American Board of Orthopaedic Surgery; served as an observer in the U. S. Army attached to the French Army in 1915-1916 and was decorated by the French government; veteran of World Wars I and II; fellow of the American Academy of Orthopaedic Surgery, Philadelphia Surgical Society, and the Texas Surgical Society; member and past-president of the Texas Orthopaedic Association, of which he was founder; associated with the Bryn Mawr (Pa.) Hospital, Pennsylvania Hospital, and the Misericordia Hospital; served on the staffs of the Robert B. Green, Santa Rosa, and Nix Memorial hospitals in San Antonio, Texas; formerly medical director of the Gonzales Warm Springs Foundation Hospital for Crippled Children in Gonzales, Texas; died in the Hospital of the University of Pennsylvania Feb. 20, aged 74.

Kretsch, Russell Woodling Ⓜ Hammond, Ind.; Indiana University School of Medicine, Indianapolis, 1925; veteran of World War I; member of the staff of St. Margaret Hospital; died Feb. 23, aged 61.

LaForge, Alvin Wilfred, Austin, Texas; the Hahnemann Medical College and Hospital, Chicago, 1911; veteran of World War I; died Feb. 21, aged 70.

Leasum, Robert Nels Ⓜ Osseo, Wis.; Jefferson Medical College of Philadelphia, 1918; veteran of World War I; on the staffs of the Sacred Heart Hospital and Luther Hospital in Eau Claire, where he died Feb. 27, aged 67.

Leyda, Paul Leighton Jr., Denver; University of Colorado School of Medicine, Denver, 1946; interned at Highland-Alameda County Hospital in Oakland, Calif.; served a residency at the St. Francis Hospital and Sanatorium in Colorado Springs, Colo., and the Veterans Administration Hospital in Denver; specialist certified by the American Board of Surgery; member of the Industrial Medical Association; captain, medical corps, U. S. Army Reserve from 1947 to 1949; formerly associated with the Lanai Community Hospital in Lanai City, Hawaii; died Feb. 24, aged 36.

Manahan, Charles Albert, Vinton, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1908; Jefferson Medical College of Philadelphia, 1909; veteran of World War I; on the staff of the Virginia Gay Hospital; died Feb. 25, aged 73.

Markoff, Samuel Tobias Ⓜ Brooklyn; Yale University School of Medicine, New Haven, Conn., 1926; member of the American Academy of General Practice; on the staff of the Brooklyn Women's Hospital; died March 6, aged 56.

Matthews, Augustus Douglas Ⓜ Ozark, Ala.; University of Alabama School of Medicine, Mobile, 1911; served as a member and chairman of the Dale County Board of Education; died Feb. 20, aged 72.

McConnell, Joseph Horton Ⓜ Galveston, Texas; University of Texas School of Medicine, Galveston, 1956; also held a degree in law; veteran of World War II and the Korean War; retired captain in the Air Force; died Feb. 24, aged 37.

McCrary, Dowell Womack, Stevenson, Ala.; Memphis (Tenn.) Hospital Medical College, 1913; died in the Jackson County Hospital, Scottsboro, Feb. 23, aged 73.

Natt, Jerome Ⓜ Roanoke, Va.; Long Island College of Medicine, Brooklyn, 1933; member of the American Academy of General Practice; past-president of the Roanoke Council for Retarded Children; died Feb. 22, aged 51.

Nutter, Edwin Hughes Ⓜ Newark, Del.; Hahnemann Medical College and Hospital of Philadelphia, 1935; interned at Homeopathic Hospital in Wilmington; member of the American Academy of General Practice; associated with the Memorial Hospital in Wilmington, where he died Feb. 24, aged 51.

O'Donnell, Reynolds Joseph Ⓜ Santa Monica, Calif.; Creighton University School of Medicine, Omaha, 1929; served on the faculty of his alma mater; veteran of World War II; vice-chief of staff, secretary and treasurer of the St. John's Hospital; member of the staff of Santa Monica Hospital; past-president of the Catholic Physicians' Guild of Greater Los Angeles and a past-president of the Creighton University Alumni Association of Southern California; died Dec. 11, aged 57.

Parker, Oliver T. Ⓜ Salida, Colo.; University Medical College of Kansas City, Mo., 1897; served on the staff of the Denver and Rio Grande Western Hospital; died Feb. 22, aged 82.

Paulson, Alvin Winfred Ⓜ Oklahoma City, Okla.; Washington University School of Medicine, St. Louis, 1932; veteran of World War II; associated with the University and Children's hospitals, and head of the outpatient department of Veterans Administration Hospital, where he died March 7, aged 51.

Peck, Anna Dixon, Oakland, Calif.; Cooper Medical College, San Francisco, 1900; served as superintendent of schools in Napa County; for many years associated with the U. S. Veterans Bureau in Washington, D. C.; died Feb. 26, aged 90.

Peck, Willena Abby Ⓜ Stow, Mass.; Woman's Medical College of Baltimore, 1900; at one time associated with the Blue Mountain (Miss.) College and the Alabama College in Montevallo, where she received an honorary doctor of laws degree; died in the Emerson Hospital, Concord, Feb. 27, aged 84.

Rininger, Harold Casper Ⓜ Evansville, Ind.; Indiana University School of Medicine, Indianapolis, 1930; veteran of World War II; on the staffs of the St. Mary's and the Welborn Memorial Baptist hospitals; died in the Barnes Hospital, St. Louis, Feb. 28, aged 52.

Riter, James Foster, Bryson City, N. C.; Jefferson Medical College of Philadelphia, 1904; veteran of the Spanish-American War; died Feb. 19, aged 80.

Roark, Walter William Ⓜ Bethpage, Tenn.; University of Tennessee College of Medicine, Memphis, 1912; died Feb. 19, aged 86.

Rogers, William Hershel, Blairsville, Ga.; Medico-Chirurgical College of Philadelphia, 1901; died Feb. 23, aged 88.

Rowat, Harry Lewis Ⓜ Des Moines, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1904; died Feb. 17, aged 80.

Schenck, Sam Moore Ⓜ Shelby, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1923; fellow of the American College of Surgeons; on the staff of the Cleveland County Hospitals; died in Manteo, N. C., Feb. 10, aged 63.

Scott, Ira Benjamin, Cleveland; Meharry Medical College, Nashville, Tenn., 1923; died in the Polyclinic Hospital Feb. 4, aged 69.

Stott, Ardenne Albert Ⓜ Bath, Maine; Tufts College Medical School, Boston, 1907; fellow of the American College of Surgeons; veteran of World Wars I and II; member of the staff of the Bath Memorial Hospital; died in the Maine Medical Center, Portland, Feb. 9, aged 75.

Straeten, Renier John Ⓜ Commander, U. S. Navy, retired, Los Angeles; John A. Creighton Medical College, Omaha, 1905; entered the U. S. Navy in 1907 and retired June 30, 1936; died Dec. 19, aged 74.

Taitz, Irvin Solomon Ⓜ Pittsburgh; Universität Basel Medizinische Fakultät, Switzerland, 1937; served on the staff of the Columbia Hospital in Wilkinsburg, Pa.; died in the Montefiore Hospital March 4, aged 48.

Vandever, Harl Fitzgerrell Ⓜ Enid, Okla.; University Medical College of Kansas City, Mo., 1907; veteran of World War I; medical director of the Enid State School; associated with the Enid General Hospital, where he died March 7, aged 74.

Wilson, Morris Wulfson Ⓜ Oak Park, Mich.; Universität Basel Medizinische Fakultät, Switzerland, 1936; served a residency in pathology at the Children's Hospital in Washington, D. C., and the Colorado State Hospital in Pueblo; specialist certified by the American Board of Pathology; member of the College of American Pathologists and the American Society of Clinical Pathologists; association with the U. S. Public Health Service terminated Sept. 29, 1946; served on the staff of the Veterans Administration Center at Mountain Home, Tenn.; died Jan. 16, aged 46.

Wolf, Morris Ⓜ Brooklyn; Long Island College Hospital, Brooklyn, 1921; died in the Long Island College Hospital Dec. 29, aged 70.

Zarbaugh, Guy Frederic Ⓜ Deadwood, S. D.; University of Nebraska College of Medicine, Omaha, 1925; veteran of World Wars I and II; died Feb. 27, aged 61.

FOREIGN LETTERS

GERMANY

Preventing Senility.—C. Hackmann (*München. med. Wchnschr.* 100:1814-1817, 1958) gave small doses of 2-(*p*-aminobenzenesulfonamide)-pyrimidine and 2-(*p*-aminobenzenesulfonamide)-methylpyrimidine to young rats. After several months he observed an improvement of the coat, increase in body weight, and a distinct improvement in the general condition, in contrast to control animals given tetracycline, chloramphenicol, and similar drugs. In all cases the treated animals lived longer than the controls. The author then repeated the experiment with old rats, and again he noticed a distinct improvement of the coat and general condition and a prolonged life, if the animals were treated for a sufficiently long time. The same results were obtained in mice. These effects were independent of the sex of the animal. The efficacy of the drugs was neutralized by simultaneously giving PABA.

In the same issue H. Hackmann and C. Hackmann reported the use of these drugs on 14 patients suffering from senile cataract. In 12 patients subjective and objective improvement of vision and in some striking improvement of the general condition were achieved. Side-effects or alteration of the blood chemistry did not occur.

INDIA

Long-Acting Sulfonamide.—K. J. Vyas treated 54 children suffering mostly from gastrointestinal and respiratory infections with sulfamethoxvpyridazine. This compound is believed to be rapidly absorbed from the gastrointestinal tract, producing a high blood concentration within a short time which is maintained for a long time. Its degree of acetylation is low, solubility in urine low, and urinary excretion slow. Its antibacterial activity is equal to that of sulfadiazine. It was given in the form of a syrup in a single daily dose of 0.5 to 1.0 Gm. every morning. No other antibacterial agent was used. An alkaline mixture was given along with it, and the duration of treatment varied from 2 to 28 days, although it was given to most patients for less than a week.

In this series 44 patients were cured, 5 had marked relief, 2 had moderate relief, and 3 were not benefited; of these 2 had infectious diarrhea, and the 3rd had chronic otitis media with chronic upper respiratory tract infection. Side-effects were met with in only three and consisted of nausea and vomiting. Most patients responded well within five days of treatment. It was observed that in patients with bronchitis the cough was the last symptom to disappear, persisting long after the acute symptoms had disappeared. Chronic otitis media was slow to respond or did not respond at all, and in seven patients with respiratory infections the tonsils remained enlarged at the end of treatment. The drug was on the whole well tolerated and easily accepted by the children.

ITALY

Vitamin D_2.—L. Papadia of the Orthopedic Clinic of Florence (*Archivio Putti*, vol. 10, 1958) studied the action of large doses of chemically pure, orally administered vitamin D_2 on the muscles of growing rats in an effort to determine how much of the change described in the skeletal muscles after administration of large amounts of cod liver oil is due to its vitamin D_2 content and how much is due to a secondary action of the oil (caused by the ease with which it turns rancid), through destruction of the vitamin E content of the diet. The amount of vitamin D_2 administered was 2 mg. per day. The duration of treatment was two, four, six, or eight weeks. In all subjects changes in muscles were found, but while the animals treated for a shorter time showed reduction of the caliber of the fibers and a crowding together of the nuclei, those treated for a longer time showed more widespread degeneration. The changes observed were similar to those previously described after the use of cod liver oil. The author concluded that vitamin D_2 given in large amounts is capable by itself of producing marked alterations in muscles.

NORWAY

Mass Radiography.—Hansen and Riddervold (*Nord. med.* 61:169-174 [Jan. 29] 1959) stated that from 1943, when it was established, until the end of 1957 the mass-radiography service has made over 4,100,000 x-ray examinations of the population over 14 years of age. Each year radiograms of about 350,000 persons are taken by means of seven units, two of which are installed on boats. Since 1948 the mass radiography has been combined with tuberculin testing and BCG inoculation. The authorities concerned were empowered to summon people to

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

these examinations. The films were read at a central office in Oslo with independent readings, since 1952, by two specialists and a control reading by a third who reexamined the films of those persons who by one or both of the first readers had been referred for follow-up examinations. Mass radiography was used most extensively in areas where there was a high incidence of tuberculosis. Of the 20 provinces in Norway 14 had been covered by mass radiography twice, 3 three times, and 1 five times. Attendance of the native population was between 72 and 84% for men and between 80 and 91% for women in the years 1949 to 1957.

In the years 1949 to 1953 between 2.8 and 4.2% of the persons examined were referred for follow-up examination. The follow-up study showed that 1.3 to 1.5 persons per 1,000 had tuberculosis, previously unrecognized in 0.07 to 0.12%. There was good correlation between the mortality from tuberculosis in each province and the incidence of new cases of active tuberculosis found. The number of infectious cases of tuberculosis was more than twice as high for men as for women in the older age groups. A corresponding difference was not found for other tuberculous changes in the lungs. Duplicate readings in 1953 of about 267,000 miniature films distributed among 29 readers showed a variation in the frequency of referrals of from 3.1 to 12.1%. The difference was essentially due to subjective factors. With unanimous reading by three specialists the incidence of infectious cases discovered by follow-up was 7.1%, with divergence among the readers of 0.8%.

SWEDEN

Convulsions in Childhood.—At the Kronprinsessan Lovisas Barnsjukhus children's hospital between 10 and 14% of the admissions from 1952 to 1956 were for convulsions. According to Dr. C. Gyllenswärd (*Svenska läkartidningen*, Feb. 6, 1959) they occur at least once in about 7% of all children under the age of 15 years. To distinguish among the 15 possible causes of a convulsion in childhood it is necessary to take the child to a hospital with a team specializing in neurology, psychiatry, radiology, surgery, physiology, and biochemistry. The author is opposed to the isolation of epileptic children in special classes. His hospital keeps in touch with some 500 children who have suffered from convulsions, and he believes that about 80% of such patients recover completely. With the drugs now available 90% of all epileptic children can be kept free of attacks, and of the remaining 10% most can achieve an appreciable reduction of their frequency. From both the medical and the scholastic points of view, most epileptic children should attend the same classes as normal children. To refer them to special schools or mix them with adult epileptics is cruel.

UNITED KINGDOM

Patent Medicines on Television.—The *British Medical Journal* of March 21 says in an annotation that anything that forces itself on the attention is apt to stir up mixed feelings. When advertisements fill the breaks between and within television programs, they find a captive audience that may be anything from inert to spellbound but is probably not highly critical. It is therefore reassuring to see that the opening words of the Independent Television Authority's principles of advertising state the general principle that it should be "legal, clean, and truthful." Clearly these are admirable precepts, and if they do not exclude the possibility of the advertisements also being nonsense, they are at least intended to prevent the use of half-truths.

In order to help the Authority maintain proper standards it has an advertisements committee, on which the BMA has an experienced representative in Dr. H. G. Dain. According to the assistant postmaster-general, who recently replied to some parliamentary questions on the subject: "All advertisements and claims for these proprietary drugs are considered by the committee and would not be approved if they were wildly extravagant." Control is thus exercised over the advertisement of medicaments on television, and the criteria relating specifically to medical products are set out in the British Code of Standards, which apply to all advertising to the general public. Their more important provisions may be paraphrased as follows:

No advertisement should (1) contain a claim to cure, (2) offer a product or advice relating to a disease for which the patient should rightly receive the attention of a physician, (3) appeal through fear, (4) offer diagnosis or treatment by correspondence, (5) claim that the product could promote virility or prevent premature aging, (6) offer any medicinal product for the purposes of slimming, weight reduction, or figure control, or (7) offer diagnosis or treatment by hypnosis.

In addition, special limitations are imposed on products advertised for the treatment of baldness and hemorrhoids. It is also an offense to advertise a product, outside of technical journals, as a remedy for cancer, tuberculosis, epilepsy, nephritis, cataract, glaucoma, diabetes, locomotor ataxia, paralysis, and venereal diseases, nor may any product be advertised in terms calculated to lead to its use for producing a miscarriage. Television attracts large sums of money for the advertisement of drugs. Much the largest group is aspirin and headache remedies followed by indigestion remedies, laxatives, and cough and cold remedies.

CORRESPONDENCE

DIABETES AND PREGNANCY

To the Editor:—The editorial in The Journal, Jan. 17, page 258, entitled "Diabetes and Pregnancy" contains the following statement: "A diet for a diabetic-obstetric patient should be given, averaging 30 calories per kilogram of increasing body weight and containing 175 to 250 Gm. of carbohydrate, 2 Gm. of protein per kilogram of body weight, and a sufficient amount of fat to complete the diet." The question concerning protein requirement of the pregnant diabetic merits discussion.

A patient who is in caloric equilibrium requires from 0.5 to 0.7 Gm. of protein per kilogram of body weight to maintain nitrogen equilibrium. The protein must be in a readily assimilable form and must contain the essential amino acids in adequate amounts. To provide an increased margin of safety, it is customary to give 1 Gm. of protein per kilogram of body weight per day. The author of the editorial proposes a protein intake of 2 Gm. per kilogram per day in pregnant diabetics. This, in a patient weighing 60 kg. (132 lb.), would, over a nine-month period, result in an intake of 16 kg. (36 lb.) of protein in excess of the amount necessary to maintain nitrogen equilibrium in a normal person. Is this large amount of protein necessary?

The fetus at term contains 630 Gm. (1.4 lb.) of protein (100 Gm. of nitrogen). The weight of the uterus, which normally is 30 Gm., increases to 1 kg. (2.2 lb.) at term. Since 75% of the uterine muscle is water, the protein increment is only 225 Gm. (0.5 lb.). The total increment of protein in the patient, resulting from the growth of the fetus and enlargement of the uterus, is barely 900 Gm. (2 lb.) There is some retention of protein by the patient, but from the teleologic standpoint, this is not at all essential. An important point is that the growth of the uterus and fetus during the first five months of pregnancy is comparatively negligible. Their combined weight at the end of this period is only 1 kg. in a woman weighing 60 kg. Beginning at the sixth month there is a rapid increase in the rate of growth of the uterus and fetus, which becomes precipitous during the eighth and ninth months.

From the foregoing one may conclude that (1) during the first five months of pregnancy a protein intake of from 1 to 1.2 Gm. per kilogram per day is sufficient and (2) during the last four months of pregnancy an intake of 1.5 Gm. of protein per kilogram of body weight per day will adequately supply the protein needs. Larger amounts of protein may be given but are not essential.

Max Wishnofsky, M.D.
615 Williams Ave.
Brooklyn 7, N. Y.

To the Editor:—Dr. Wishnofsky's points concerning the dietary needs for a diabetic-obstetric patient are well taken. The requirement of protein in the diet of such a patient who has had adequate protein intake before pregnancy is about 1.5 Gm. of protein per kilogram of body weight per day, but larger amounts of protein are given if the patient has not had adequate protein intake to make up for the past deficit. The optimum aim is nearly 2 Gm. of protein per kilogram of body weight to insure that the mother and fetus get sufficient protein and also to prevent possible toxemia. Although the cause of toxemia of pregnancy is conjectural, it is believed by various investigators that a high-protein, well-balanced diet acts as a preventive of toxemia of pregnancy. Many pregnant diabetic women are on a low-protein-intake diet because of the high cost of a high-protein diet. Others find it difficult to ingest 2 Gm. of protein per kilogram of body weight per day. A good nutritionist can be of aid in this connection.

Boston 15.

DATA ON BLOOD DONORS WANTED

To the Editor:—I am interested in securing blood samples from donors who are suspected of being carriers of viral hepatitis. In our laboratory, we wish to run a battery of liver function tests on these samples and hope to obtain more information on the number of suspected carriers who show abnormal results in these tests. We wish to study donors whose recipients have acquired viral hepatitis after transfusion, but only in those cases in which a single transfusion was given. Thus, we are interested only in so-called single donors. Drs. John Neefe and John G. Reinhold and I, with a number of our younger associates, have been interested in the problem of rejecting donors for transfusion who are potential carriers of viral hepatitis. Two of our papers were published in The Journal, one in the March 27, 1954, issue and one in the March 31, 1956, issue. Physicians knowing of cases of viral hepatitis occurring after a single transfusion are requested to write me for more precise information on submitting a serum specimen and clinical data on the blood donor for our evaluation.

MISCELLANY

THE MEDICAL TECHNOLOGIST AND THE DOCTOR

Robert B. Robins, M.D., Camden, Ark.

As a practicing physician I have an interest in the work of medical technologists and the other professional and technical personnel who assist me and my colleagues in daily practice. I know from experience how important their services are to the teamwork necessary for modern medical care.

As a member of the Board of Trustees of the American Medical Association I also have an interest from the organizational point of view. The A. M. A. has an important committee now studying all phases of the problem of promoting cooperation and rapport between the medical profession and persons in the so-called paramedical areas. That committee, in a progress report at the Clinical Meeting in Minneapolis last December, described this as "one of the most complex problems on the American medical scene today." The committee pointed out that more than 60 groups are functioning in the ancillary or paramedical areas.

You gain a perspective on the complexity of this subject by looking at the growth and development which have taken place in the field of medical technology. In the early days of the clinical laboratory the pathologist was just beginning to be recognized as a necessary medical specialist, and he performed his own laboratory tests. As laboratory medicine developed, pathologists found they needed help; so they began to train assistants to perform the simpler tests. The profession of medical technology was born around the time of World War I.

In those early days the few commercial schools that were established offered training that was inadequate, and their fees were sometimes exorbitant. Realizing that laboratory medicine was developing rapidly and that something must be done to standardize the training of laboratory assistants, the American Society of Clinical Pathologists in 1928 established the Registry of Medical Technologists.

This registry has become recognized by leading medical and hospital groups as the only authoritative qualifying body in the field. It has developed the status of the medical laboratory worker to a high professional level by raising the educational requirements and broadening and improving the technical training. The requirements established by the registry are recognized by such medical organizations as the American Medical Association, the American College of Surgeons, the American College of Physicians, the American Hospital Association, the Catholic Hospital Association, and by other pathologists, physicians, and hospital superintendents. Those requirements also are strongly emphasized by the American Society of Medical Technologists in its career guidance publications directed toward young people planning to enter this field.

In their periodic visits to hospitals staff representatives of the American College of Surgeons, the American Hospital Association, and the American Medical Association—who also are field representatives of the Joint Commission on Accreditation of Hospitals—carefully observe whether workers in the clinical laboratories have registry certificates. The registry, therefore, while purely voluntary and noncoercive, is universally accepted as the recognized authority for qualifying medical technologists in the United States.

In the past few years there has been great progress in the development of new laboratory aids to help the doctor in providing the patient with the best medical care, and year by year techniques have become more complex and specialized. To unravel major problems in diagnosis or treatment physicians today frequently seek the help of biochemists, biophysicists, bacteriologists, histochemists, experts in isotope techniques, and others. The doctor, of course, cannot be expected to master all the testing techniques, so he must depend on technicians and pathologists for help.

The entire March, 1959, issue of *Medical Clinics of North America* was devoted to a symposium on the rationale and clinical interpretation of laboratory tests. The subjects covered included practical tests of gastrointestinal function, liver function, pancreatic function, pulmonary function, kidney function, and thyroid function; tests for clotting disorders, leukemia, and diabetes; and other subjects, including a variety of recently developed laboratory procedures.

The field of medical technology, like the medical profession itself, has become so complex that the registry now issues several different types of certificates, in addition to the general certification which has been given for many years. For example, there is the specialist certification, as well as differ-

---

Read before the Louisiana State Society of Medical Technologists, Monroe, La., April 17, 1959.

ent kinds of certificates in histological technique, chemistry, microbiology, blood banking, and exfoliative cytology.

Through the years, with all these technical developments unfolding at an accelerated pace, medical technologists have worked constantly to improve their standards and qualifications. They have done this without any kind of governmental compulsion, control, or licensure—national, state, or local. In fact, one of the brightest spots in the entire paramedical picture is the excellent cooperation which has long existed among the American Medical Association, the American Society of Clinical Pathologists, that society's Board of Schools and Board of Registry, and the American Society of Medical Technologists. These groups have worked closely together in establishing and maintaining high standards of education, technical training, and voluntary registration for medical technologists.

You probably know that the A. M. A. Council on Medical Education and Hospitals acts as the inspection and approval agency for schools of medical technology. By November, 1958, the number of approved schools had increased to 688, with an enrollment of more than 3,000 students. The last annual report of the council showed increases in enrollment and number of graduates which were attributed to the effective recruitment program of the National Committee for Careers in Medical Technology. There now are at least 24,000 registered medical technologists, and there are many who are not registered. The needs of the future will require greater and greater effort. Indicative of the trend is the continuing increase in the number of medical technology schools with college or university affiliations. And effective in January, 1962, the entrance requirement for approved schools will be increased from two to three years of pretechnical college education.

These developments mean that all of us will have to intensify our cooperative efforts to recruit young people with an aptitude for this field, to maintain and constantly improve the standards of education and training, and to promote an ever higher proportion of qualified, registered medical technologists.

While this growth and development has been taking place in the field of medical technology the same thing, in varying degrees, has been happening in other paramedical areas. The medical team has grown in both size and diversity. Working for or with physicians in modern medicine are not only nurses, pharmacists, and medical technologists but also x-ray technicians, occupational therapists, physical therapists, psychiatric social workers, medical record librarians, medical record technicians, and many other types of technical personnel. In addition, there is a large group of persons holding advanced degrees, such as the Ph.D., who are engaged in medical and allied teaching. They also participate directly or indirectly in the care of patients. They are especially active in such preclinical fields as anatomy, biochemistry, microbiology, pharmacology, and physiology.

The best estimate so far is that there are 10 paramedical personnel for each physician. You can see that, from the standpoints of both size and diversity, the problem of promoting closer coordination and higher standards is an enormous one.

Earlier I mentioned an A. M. A. committee that is studying all phases of this subject. Creation of this committee by the Board of Trustees of the American Medical Association reflects a sincere desire to improve the quality of medical care in America by bringing together the too often divergent interests that have evolved during the rapid progress in all fields of medical care. There will be concerted effort to develop an atmosphere in which all will work harmoniously in the best interests of the patient.

Continued advances in medical care and in the art and science of medicine will certainly be in direct relation to the medical profession's ability to understand and work cooperatively with the many disciplines that contribute to the total care of the patient. The precise nature of these future cooperative efforts remains to be determined. Our immediate aim is to gain a broad, over-all view of the various disciplines that are closely related to medicine. Later, there will be more detailed study of particular phases and suggested courses of action.

The House of Delegates of the American Medical Association adopted a resolution in December, 1958, encouraging the voluntary registration of paramedical personnel who assist physicians. At the same time it expressed opposition to the extension of governmental licensure and governmental registration. However, the House requested the committee on paramedical areas to expand its study to include this phase of the problem.

Prominent in the medical profession's thinking is the concept of teamwork and the realization that physicians must offer more active leadership and guidance to ancillary groups. Medical technicians are our fellow workers and our allies in reaching the goal of improved patient care. We want to understand their problems, and we want them to understand ours.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

A Syndrome Developing After Myocardial Infarction. H. P. Groeneveld. Nederl. Tijdschr. geneesk. 103:153-154 (Jan. 24) 1959 (In Dutch) [Amsterdam].

In connection with the case history of a 57-year-old man, who was hospitalized with a diagnosis of heart infarct, the author calls attention to the postmyocardial infarction syndrome which was first described by Dressler in THE JOURNAL (160: 1379 [April 21] 1956). The syndrome is characterized by a combination of pleurisy, pericarditis, and sometimes pulmonary infiltration. The patient presented had had diabetes mellitus for 15 years, and for a period of 6 months preceding the myocardial infarction he had had typical anginal attacks. On examination, pericardial as well as pleural friction rubs could be heard. The left side of the heart was enlarged. The electrocardiogram indicated a posterobasal infarct. The pericardial and pleural friction rubs as well as the cardiac enlargement persisted for a considerable period, but the course was favorable. The patient was treated with insulin and anticoagulants, and was discharged from the hospital after 9 weeks. The author feels that the postmyocardial infarction syndrome is not rare, and that it should be thought of, when there are symptoms suggestive of the extension of the heart infarct, cardiac enlargement, and pulmonary infarct. Dressler found prednisone therapeutically effective but did not employ anticoagulants.

The Low-Salt Syndromes in Congestive Heart Failure. A. Vogl. Am. J. Cardiol. 3:192-198 (Feb.) 1959 [New York].

The author summarizes the current concept of the "low-salt syndromes" and their management in patients with congestive heart failure as follows. The low-salt syndrome is not an entity either clinically or biochemically but represents a group of loosely related disorders. The two main types are (1) an acute or subacute form which develops during intensive diuretic treatment and (2) a chronic form which evidently cannot be attributed to excessive diuresis, since the finding of a low concentration of sodium and chloride in the serum can connote either electrolyte loss or water retention. The differentiation between these two states is made largely on clinical grounds. In most patients there is probably a combination of both factors. The principles of management are different for the depletion types (hypochloremic acidosis and hyponatremia) and the dilution types (lowering of the serum sodium concentration due to dilution of the sodium in the extracellular fluid), but in a given patient treatment remains largely empirical and must be guided by clinical as well as laboratory observation. Correction of the altered electrolyte concentrations is more likely to be achieved if treatment is not limited to appropriate administration of sodium and chloride, but includes the restriction of fluid intake and the concurrent administration of potassium.

The iatrogenic production of a "low-salt syndrome" is not an inevitable risk whenever a low-salt diet and potent diuretics are employed. It can, by and large, be avoided if treatment is individualized, and if the effect of the diuretic procedures is critically evaluated from day to day. Practical treatment principles are presented.

Treatment of Hypertension in the Ambulatory Patient. J. H. Moyer and J. Beem. Am. J. Cardiol. 3:199-213 (Feb.) 1959 [New York].

The authors report observations on 129 unselected patients with diastolic hypertension of all grades of severity, who were studied at the hypertension outpatient clinic of the Hahnemann Hospital in Philadelphia. Blood pressure elevation of adequate severity and for a prolonged period of time will definitely produce vascular changes in the brain, the heart, and the kidneys. Effective reduction of blood pressure may completely arrest these vascular changes regardless of the method used for the reduction of blood pressure. Although the changes may be arrested, renal function rarely returns to normal. Hypertension aggravates and hastens the development of arteriosclerosis. Reducing the blood pressure arrests this hastening process, but still arteriosclerosis progresses, just as it does in the normotensive person. The method used for the reduction of blood pressure is prob-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

ably not important, insofar as arresting the vascular changes associated with hypertension is concerned. The important thing is that the blood pressure be reduced effectively. This the surgeon can do, particularly when he employs concurrent medical therapy. The authors would concur with this approach, just as long as the blood pressure is severe enough to warrant surgical therapy and the surgeon is proficient at performing sympathectomies. On the other hand, when the psychiatrist or the general practitioner or the internist, who carries psychiatric overtones, can "talk the blood pressure down," this is to be considered good therapy. The authors, being neither psychiatrists nor surgeons, prefer to use drugs, and their own results with psychotherapy (and placebo) have been poor.

A *multipronged approach is outlined,* based on the severity of the hypertensive disease. Mild hypertension can be controlled with chlorothiazide, given to deplete body sodium by increasing its excretion. The administration of this drug may be continued indefinitely as a background medication for all antihypertensive drugs. This is probably the most effective measure for the reduction of blood pressure. Then the sympathetic nervous system is blocked by various methods. The centrally acting drugs are used first. The commonest ones are rauwolfia and hydralazine. Usually in milder cases rauwolfia may be given an initial trial alone, and if the patient needs additional therapy, he may receive hydralazine (Apresoline). In patients with moderately severe hypertension, hydralazine combined with rauwolfia may be given a therapeutic trial.

For patients with more severe hypertension, when the diastolic blood pressure is fixed above 120 to 130 mm. Hg, the use of glanglionic blocking agents, such as mecamylamine or pentolinium, is indicated. Of 31 patients with malignant hypertension, 13 were treated and 18 were untreated. Seventeen of the latter group have died, while of the treated patients 11 are living and 2 are dead. Eleven of the 18 untreated patients died of renal failure and uremia. Treatment of patients with malignant hypertension has completely altered the cause of death, and, when treatment was started as long as the blood urea nitrogen level was normal, patients rarely died of renal failure. The cause of death in treated patients usually was a cerebrovascular accident or a coronary occlusion.

Digitalis and Atrial Tachycardia with Block: A Year's Experience. B. Lown, F. Marcus and H. D. Levine. New England J. Med. 260:301-309 (Feb. 12) 1959 [Boston].

Although numerous recent reports emphasize the increasing frequency of digitalis poisoning, there is as yet little appreciation of the digitalis-induced atrial arrhythmias, the prototype of which is paroxysmal atrial tachycardia with block. The present report is based upon an examination of episodes of paroxysmal atrial tachycardia with block studied at the time of their occurrence in 1957 at the Peter Bent Brigham Hospital, Boston. Thirty-two episodes of paroxysmal atrial tachycardia with block were diagnosed in 23 patients. The criteria for the diagnosis were as follows: an atrial rate usually between 150 and 200; a demonstrable change in the morphology of the P wave; an isoelectric baseline between consecutive complexes in all leads; and the presence of atrioventricular block, either spontaneous or induced by carotid sinus pressure or other vagal maneuvers. The role of digitalis was established on the basis of the clinical circumstances chronologically *related to the onset and cessation of the arrhythmia.* Digitalis was considered to be the cause (1) if the arrhythmia developed during digitalization or after an increase in maintenance dosage and was abolished by withdrawal of the drug; (2) if the arrhythmia occurred in a digitalized patient immediately after a mercurial-induced diuresis with a substantial weight loss; (3) if the arrhythmia appeared after an event known to enhance digitalis effect, such as potassium loss induced by vomiting, diarrhea, or hemodialysis; (4) if subjective and objective signs of digitalis overdosage appeared with the onset of paroxysmal atrial tachycardia with block and disappeared when the drug was withdrawn.

Twenty-four of the 32 episodes of paroxysmal atrial tachycardia with block were due to digitalis intoxication. In 4 of the 24 episodes simply the discontinuance of digitalis and of diuretic measures restored a normal mechanism. In 2, the administration of digitalis was continued; both patients died. In the remaining 18, measures in addition to stopping digitalis were required: Five episodes were controlled by the oral or intravenous use of potassium; in 10 reversion was achieved by the combined use of potassium and procainamide; and 3 were controlled by procainamide alone. It appears mandatory to stop digitalis and suspend the use of diuretics until a normal mechanism is established. During the past 5 years there has been no reduction in the incidence of paroxysmal atrial tachycardia with block at the Peter Bent Brigham Hospital. The continuing high incidence of this and other manifestations of digitalis intoxication is due to a number of factors. There is no method that permits prediction of optimal digitalis requirements; digitalization, therefore, is frequently carried either overtly or inadvertently to a toxic endpoint. The state of digitalization, like all biological phenomena, is not static. An adequate maintenance dose at one time may prove inadequate or excessive at a later period. Furthermore, the margin between a therapeutic and a toxic dose narrows with advancing age and increasing heart failure. Lastly, there is an increasing dependence upon electrolyte manipulation in the management of patients with heart failure. Losses of potassium that may attend such measures predispose to intoxication.

Routine Blood Control and Prevention of Medicamental Hemopathies. T. K. With. Ugesk. læger 121:77-81 (Jan. 15) 1959 (In Danish) [Copenhagen].

Routine blood cell counts are of doubtful value in the prevention and early diagnosis of granulocytopenia induced by drugs and can at best be an adjuvant to clinical control. Clinical control consists in impressing on the patient at every consultation the risk involved in taking the drug in question and the paramount importance of immediate withdrawal of the drug and immediate contact with the physician for blood control in case of malaise, fever, sore throat, or sudden exanthem. The blood control must include both leukocyte and differential counts. Normal values in case of clinically alarming symptoms do not exclude a developing granulocytopenia. On normal values the count should be repeated daily for a week or until the symptoms have disappeared. The control must be maintained for the first 2 weeks after withdrawal of the medicament.

SURGERY

Multiple Simultaneous Complications of Peptic Ulcer. S. W. Moore and F. W. Fuller. Am. J. Surg. 97:184-190 (Feb.) 1959 [New York].

Between Jan. 1, 1940, and March 1, 1957, there were 969 admissions to the surgical wards of the New York Hospital for perforated, bleeding, or obstructed peptic ulcer. This group consisted of 775 different patients. Of the 969 admissions, 89 (9.2%) represented 82 different patients with a combination of 2 or 3 complications. The remaining 880 admissions represented 693 patients with only a single perforation, hemorrhage, or obstruction. In the entire study there were 152 patients with perforation, 678 with hemorrhage, and 233 with obstruction. In the group with multiple complications, there were 32 with perforation, 74 with hemorrhage, and 77 with obstruction. Thus, 21% of all patients with perforation had concurrently 1 or 2 other complications, as did 11% of all with hemorrhage, and 33% of all with obstruction. Fifteen of the 82 patients in the multiple entity group died, representing a mortality rate of 17% of 89 admissions in this group. Thirty-six of the 693 patients in the single entity group died, representing a mortality rate of 4% of the 880 admissions in this group. These findings showed that nearly 10% of the patients had more than one of the 3 complications (perforation, hemorrhage, and obstruction), and that such combinations produced a mortality 4 times as great as among patients with only one such complication.

There was a strong association of severe unrelated diseases, especially malignant tumors, in the multiple entity group. Twenty-one (over 25%) of the 82 patients were thus affected. That these associated lesions are often in an early and previously undiagnosed state at the time of the admission for the combined complications suggests that they may serve to exacerbate an existing ulcer tendency and that a severely complicated peptic ulcer may indeed be an early warning signal of their presence. A vigorous examination, especially for pulmonary disease, is indicated in every patient surviving combined complications of peptic ulcer. The triple combination of perforation, hemorrhage, and obstruction is much more common than previously believed, having occurred in 5 of the 82 patients with multiple complications.

The high mortality rate among patients with combined perforation and hemorrhage, when the hemorrhage is massive, was again confirmed. A search for multiple ulcers in the stomach and duodenum should be made whenever the operation of plication is done in a case of perforation, and primary gastric resection should be strongly considered if they are found. Simple gastroenterostomy, gastroenterostomy with vagotomy, or primary gastric resection should be performed for an obstructed perforated ulcer. Such an ulcer usually involves both the anterior and the posterior pyloric walls and makes more likely the occurrence of a massive postoperative hemorrhage as well as dehydration and electrolyte imbalance from pyloric obstruction, unless the additional procedure is performed. When actually confronted with a massive hemorrhage occurring near the time of perforation, the surgeon may be powerless because of the desperate general condition of the patient. Vigorous blood replacement coupled with immediate gastric resection usually offers the only hope for survival. The occurrence of multiple combined complications is a positive indication of advanced, intractable ulcer disease requiring definitive surgical treatment, usually gastric resection, at the earliest possible moment.

Acute Cholecystitis. J. J. Byrne. Am. J. Surg. 97:156-172 (Feb.) 1959 [New York].

The author presents a pathological and clinical review of 82 women and 52 men, between the ages of 24 and 91 years, with acute gallbladder disease, who were admitted to the surgical service of the Boston City Hospital. Microscopic examination of 75 pathological specimens obtained from these patients provided good evidence that gallbladders may be easily operated on within the first 10 days of an acute attack, and that the earlier this operation is performed, the less chance there is for subsequent

Poison Labeling Legislation . .
Say Military Should Control Medicare . .

HOUSING BILL FACES VETO, LAWMAKERS WARN

Congressional Republican leaders assailed the housing bills approved by the House and Senate as "budget busting." They contended measures calling for such high levels of spending probably would be vetoed by President Eisenhower.

A House-Senate conference committee, composed of members of House and Senate banking committees, was resolving differences in the two measures. It was expected, however, that the final compromise would call for more spending than proposed by the administration.

A veto, if sustained, would jeopardize the fate of provisions of both measures authorizing the Federal Housing Administration to insure loans for construction of proprietary nursing homes, provisions backed by the American Medical Association. However, such loan guarantees could be approved later as separate legislation, or as part of another, scaled-down housing measure. They are not controversial.

In addition to the nursing home program the House-approved legislation authorized about 65 million dollars annually in direct federal loans for construction of college housing facilities for interns and nurses, 40 million dollars more than the budget requested. There was a similar provision in the Senate bill.

NEW PATIENT CARE PLAN STUDY BY PHS

After a two-year study the Public Health Service has offered a blueprint program for a new type of hospital operation known as "progressive patient care." The new system, which the PHS said "shows promise and which, in recent months, has aroused widespread interest," is based on the principle of using separate sections of the hospital to treat patients according to the severity of their illnesses.

For example, those recovering from major surgery or ill enough to require constant surveillance would be placed in special units in one part of the hospital. As the patients progressed in health, they would be moved to other sections with patients in similar stages of recovery.

The study, published in an 87-page document, was conducted by the PHS and private experts on hospital operations. It was headed by Dr. Jack C. Haldeman, chief of the division of hospital and medical facilities of the PHS Bureau of Medical Services.

In a statement Dr. Haldeman said, "since the general hospital is a focal point for community health, the progressive patient care concept envisions the general hospital of the future as a community health center—the focus for both outpatient and inpatient care; as much concerned with the care for the long-term patient (including the mentally ill and tuberculous) as it is now for the care of the short-term patient, as much concerned with extending good medical and hospital care to the home by assisting the physician in the care of the patient at home as with assisting him with the care of the patient in the hospital."

There are five phases of progressive patient care—intensive care, intermediate care, self care, and long-term care, all within the hospital. In addition, organized home care would be provided.

The most seriously ill, with certain exceptions, would be placed in the intensive care unit—a room with five or six patients under the constant surveillance of a professional nurse and a practical nurse or nursing aide around the clock.

The intermediate care unit would be more nearly patterned after conventional hospital units—that is, a floor of rooms with a staff of floor nurses. The self-care unit would consist of 16 to 20 beds, preferably in single rooms with private toilets, and staffed by one professional nurse and two aides or two practical nurses. Only a practical nurse or nurse's aide would be needed for the night shift.

The long-term care unit would be for chronically ill patients needing hospital attention and others who need lengthy care. In some respects it would assume the functions of a nursing home. A larger staff would be required than for the self-care division. The long-term unit might be feasible only for larger hospitals.

The home care program would provide coordinated services to patients at home through family physicians, public health nurses, and social caseworkers, assisted by clerical services at the hospital.

SMATHERS INTRODUCES SELF-EMPLOYED RETIREMENT BILL

Sen. George Smathers (D., Fla.) introduced a bill to encourage the self-employed to invest in retirement plans that is almost identical to the legislation that easily cleared the House earlier this year.

The lawmaker is a member of the Senate Finance Committee that is scheduled to hold hearings on the measure later this year. The bill, sponsored in the House by Rep. Eugene J. Keogh (D., N. Y.), provides tax deferral of 10% of net income up to $2,500 for self-employed such as physicians and lawyers who set money aside for their retirement in qualified plans.

Unlike the House measure the Smathers bill would take effect in the taxable year 1961, rather than 1959. The change, Smathers said, would "meet opposition to the pending proposal which was predicated primarily on revenue loss."

"Under the present federal tax structure, it is clear that preferential income tax treatment is given those wage earners and salaried employees whose employers set up qualified pension and/or profit-sharing plans in their behalf," said the senator.

Two other senators have also introduced the measure; they are Sen. Thruston B. Morton (R., Ky.), G. O. P. national chairman, and Sen. Estes Kefauver (D., Tenn.).

HEALTH STANDARDS URGED FOR ALIENS WITH INFECTIOUS DISEASES

The federal government should draw up regulations to bar admission to the United States, temporarily, of aliens with communicable diseases, the American Medical Association told Congress. The A. M. A. said the Public Health Service should be authorized to make recommendations concerning the issue of visas at the port of departure. Many severe illnesses are now automatically grounds for refusing admission, but not all are covered, nor are examinations soon before departure for this country requested.

In a letter to Sen. James O. Eastland (D., Miss.), chairman of the Senate Judiciary Committee, Dr. F. J. L. Blasingame, A. M. A. Executive Vice-president, said such regulations would protect not only American citizens but the aliens as well.

A Senate judiciary subcommittee is considering, among other bills, a House-passed measure that would extend permission for alien children suffering from tuberculosis to be admitted to this country, provided certain safeguards are met. It is designed mainly for Korean orphans adopted by American citizens.

In his letter, Dr. Blasingame said, "It is our hope that those who have undertaken the task of transporting these unfortunate children to new homes will continue their work. It is our belief, however, . . . that more stringent health controls are necessary."

Some children have entered the U. S. suffering from pneumonitis, scabies, and other communicable diseases, he noted.

HARZARDOUS SUBSTANCE BILL INTRODUCED

A measure requiring the precautionary labeling of hazardous substances not covered by the food and drug act has been introduced by Rep. Thomas B. Curtis (R., Mo.), a member of the influential House Ways and Means Committee.

The bill was drafted by the Committee on Toxicology of the American Medical Association after a number of conferences with industry, government, public health, and consumer groups. The measure received the favorable consideration of over 60 national organizations including organized labor, as well as a cooperative review from chemical trade associations who will be affected.

Representative Curtis, in introducing the measure, noted that, in recent years, "many new compounds for household, commercial, and industrial use have been introduced which are outside the scope" of the food and drug laws labeling provisions. "There is no broad law," he declared, "which requires th precautionary labeling of hazardous substances a the national level."

The model bill drafted by the A. M. A. Committee "reflects current knowledge of hazardous chemicals and the conditions under which they are employed," the lawmaker said. "One of the fundamental problems in reducing poisoning is the lack of identification of hazardous ingredients and precautionary labeling on the wide variety of small packaged chemical items in general use and the influence of this lack of identification on their careless and improper handling and storage.

"By requiring statements of harmful ingredients on labels, the bill will also aid physicians in the diagnosis and treatment of poisoning," said Representative Curtis.

It is not now requested that the labels on some products, such as some household cleansers for example, list harmful substances, even though consumption by children or constant exposure to adults could produce harmful effects.

MILITARY REJECTS PROPOSAL FOR CIVILIAN CONTROL OF MEDICARE

Dr. Frank B. Berry, Assistant Secretary of Defense, Health, and Medicine, said the Defense Department should continue to administer the "Medicare" program, providing treatment in civilian hospitals for qualified dependents of military personnel.

The official notified Congress that the department opposes suggestions made by the Florida Medical Association to provide an insurance program for such dependents and to transfer control to the Department of Health, Education, and Welfare, since those being treated are civilians. The proposals by the Florida association were made before a House appropriations subcommittee. Representatives of the association made it clear they were not criticizing the Defense Department in offering the recommendations.

Dr. Berry said military families are part of the military community, "and there appears to be no reason to separate them medically.

"Due to the fact that dependents are a highly transient population, there are many problems connected with the administration of any program of medical benefits that can be handled only by the uniformed services," he said.

PERSONNEL

Dr. F. J. L. Blasingame, Executive Vice-president of the American Medical Association, announced the resignation of Dr. Cyrus H. Maxwell of the A. M. A.'s Washington Office. Dr. Maxwell, who was responsible principally for the Association's liaison work with the Senate, has accepted a position with the Public Health Service in the Chronic Disease Branch of the Division of Special Health Services. His major assignment will be to work as a PHS representative in planning and carrying out the White House Conference on Aging.

...WHEN YOU PRESCRIBE NEW

MORNIDINE™

(BRAND OF PIPAMAZINE)

A new drug with specific effectiveness in nausea and vomiting of pregnancy, Mornidine eliminates the ordeal of morning sickness.

With its selective action on the vomiting center, or the medullary chemoreceptor "trigger zone," Mornidine possesses the advantages of the phenothiazine drugs without unwanted tranquilizing activity.

Doses of 5 to 10 mg., repeated at intervals of six to eight hours, provide excellent relief all day. In patients who are unable to retain oral medication when first seen, Mornidine may be administered intramuscularly in doses of 5 mg. (1 cc.).

Mornidine is supplied as tablets of 5 mg. and as ampuls of 5 mg. (1 cc.).

POLYPS OF THE COLON AND RECTUM

A FOUR-YEAR TO NINE-YEAR FOLLOW-UP STUDY OF FIVE HUNDRED THIRTY-SEVEN PATIENTS

J. Alfred Rider, M.D., Joseph B. Kirsner, M.D., Hugo C. Moeller, M.D.
and
Walter L. Palmer, M.D., Chicago

In a six-year period, 9,669 proctosigmoidoscopic and x-ray examinations resulted in detection of polyps in 537 patients. A vigorous follow-up program from four to nine years later revealed that new polyps developed in approximately 40% of these patients, indicating need for frequent reexamination. Incidence of carcinoma of the colon was twice as high in patients with multiple polyps as in those with single polyps. Local removal appeared to be adequate treatment for benign polyps and for adenocarcinoma within reach of the proctosigmoidoscope.

IN A previous paper[1] the incidence of polyps of the colon and rectum and their relationship to carcinoma was reported in 7,487 patients undergoing proctoscopic and x-ray surveys as part of routine gastrointestinal examination during the interval from Jan. 1, 1947, to Dec. 31, 1951. Polyps of the rectum or colon were found in 401 patients. From Jan. 1, 1952, to Dec. 31, 1952, 136 additional patients with polyps were discovered in a series of 2,182 similar examinations. Thus, 537 patients with polyps were noted among 9,669 undergoing routine examinations in a period of six years, an incidence of 5.5%.

Some of the original 401 patients were reexamined at least yearly from 1947 to 1951. But from Jan. 1, 1952, to Dec. 31, 1956, a vigorous attempt was made to persuade each of the 537 patients to return yearly for examination. This report is based on the four-year to nine-year follow-up survey.

The purposes of the present study were (1) to determine the practicability of a long-term program of periodic reexamination of patients of this type; (2) to determine the rate of formation of new polyps and the possible relationship of these lesions to carcinoma of the colon; (3) to observe the fate of patients whose polyps presented early malignant change and yet were excised locally; (4) to evaluate the diagnostic roles of x-ray examination and proctosigmoidoscopy; and (5) to attempt to determine whether a systematized examination of patients prone to develop polyps, and the consequent early detection and treatment of malignant and premalignant lesions, would result in a higher rate of curability of carcinoma.

Practicability and Cost of Program

Problem of Patients' Cooperation.—Cooperation of the patients is essential in any long-term follow-up study. Since this program was designed to select

subjects consecutively, no attempt was made in advance to determine the willingness of the patients to participate; nevertheless, the over-all response was encouraging.

A yearly letter was sent to each of the 537 patients, explaining the significance of the program and inviting their return for examination at no cost.

TABLE 1.—*Patients Reexamined Each Year, 1953-1956*

	Patients			Examinations, No.				
	Dead		Living					
Yr.	At Beginning of Year	During Year		Proctoscopy	X-Ray	Both	Examinations Total	Total Reexamined, %
1953	26	16	495	81	7	266	354	71.5
1954	42	15	480	42	11	272	325	67.7
1955	57	6	474	25	19	282	326	68.8
1956	63	7	467	38	18	277	333	71.3

If no reply was received, a second letter was sent. The third attempt consisted of a registered letter. If these measures failed, the patient was called on the telephone at home or at work. In individual cases relatives or family physicians were helpful in reaching the patients for return examination.

The general results seem excellent. Of the 537 patients 498 (92.7%) had at least one follow-up examination. A total of 149 patients participated in at least four consecutive years of follow-up study. [illegible] patients cooperated from the outset; others, [illegible]erating initially, participated in the second, [illegible] fourth years either because their attitude changed or because they had developed a medical problem. Only 39 patients (7.3%) failed to return during the course of the study, although presumably they were alive. Twenty-three individuals refused to return, offering reasons such as good health, antagonism toward the hospital or its personnel, age, the inconvenience or unpleasantness of the examination, or failure to understand the significance or necessity of the program.

Table 1 summarizes the yearly distribution of the total number of reexaminations during the last four years of the study. The high percentage of surviving patients reexamined during 1956 (71.3%), identical with that during 1953 (71.5%), reflects the patients' splendid cooperation.

Cost of Program.—The practicability of the program depended in large measure on the willingness of the staff to provide follow-up examinations at no cost; for, as a rule, no charge was made for the proctosigmoidoscopy and follow-up visits. The yearly x-rays of the colon were financed largely by a grant from the National Institutes of Health, although in some cases the patients paid for them. The department of roentgenology performed the examinations at the bare cost of the materials.

Although the exact cost per individual patient or individual examination is difficult to estimate, the cost of the entire program can be approximated by totaling the amount contributed by the Public Health Service during the five years of the study, the amount of service donated by the staff in terms of the monetary value of the proctosigmoidoscopic examination, and the subsidy by the department of roentgenology in terms of income forfeited. No attempt has been made to place a monetary value on the time donated by us for our roles in organizing and supervising the project, performing examinations, analyzing data, or submitting annual reports.

The estimated contribution of each of the above participants to the "polyp project" from Jan. 1, 1952, to Dec. 31, 1956, was as follows: National Institutes of Health grants, \$48,104; proctoscopic examinations (1,618 at \$10 each), \$16,180; subsidy by department of roentgenology for x-rays of the colon (1,354 at \$18 each), \$24,372. According to these estimations the total cost of the study was \$88,656, representing an average cost of approximately \$195 per original patient for the entire study. Similar low-cost rates will not be possible for future follow-up projects.

Formation of New Polyps and Relationship of Polyps to Carcinoma

Rate of Formation of New Polyps.—Of the 537 patients 372 had follow-up examinations four or more years after their original polyps were discovered. The rate of formation of new polyps of the colon in this group was very high, 153 patients or 41.1%.

As noted in our previous report[1] patients with multiple polyps at the original examination manifested a greater tendency to develop new polyps than patients with single polyps, although in both groups the rate of new formation greatly exceeded the 5% expectation for the general population. In the patients with multiple polyps the rate of new formation was 55.7%; in those with single polyps, 38.5%.

Table 2 shows in detail the distribution of patients by year of follow-up examination. The percentage of new polyp formation ranged from 9.3 to 15.9; during the last four years the yearly rate of recurrence approximated 10%. Thus, the year of follow-up examination seemed to make little difference with respect to the percentage of patients found to have developed new polyps.

TABLE 2.—*Distribution of Patients Participating in Follow-up Studies by Rate of Recurrence*

		Patients with New Polyps, No.			
				Combined Total	
Follow-up Period, Yr.	Total Returning, No.	Originally with Single Polyps	Originally with Multiple Polyps	No.	%
1	392	31	18	49	12.5
2	271	34	9	43	15.9
3	311	33	10	43	13.8
4	310	28	14	42	13.5
5	249	23	5	28	11.2
6	154	14	1	15	9.7
7	107	10	0	10	9.3
8	67	6	1	7	10.4
9	30	3	0	3	10.0

The histological diagnoses[1] of the original polyps also appeared not to correlate significantly with the rates of new polyp formation (table 3), except for a slight tendency toward fewer new polyps in the group with benign lesions than in those with malignant polyps; but this difference is of doubtful significance because of the small size of the samples.

Relationship of Polyps to Carcinoma of the Colon.—The incidence of carcinoma of the colon in 9,132 patients without polyps was approximately 2%. Among the 537 patients with polyps, the incidence of carcinoma in the polyps was 5.8% (not including adenocarcinoma or associated colonic carcinoma).

Table 4 lists the original pathological diagnoses[1] with respect to single and multiple polyps. In the patients with single polyps 19 had carcinomatous polyps and 33 had associated carcinoma of the colon, an incidence of 11.6%; whereas in the patients with multiple polyps 12 had carcinomatous polyps and 6 had associated carcinoma of the colon (20.7%). The total incidence of carcinoma, either associated with polyps or in the polyps, exclusive of adenocarcinoma, was 13%. If adenocarcinoma is added, the combined incidence of malignant polyps and/or associated carcinoma was 32.2%.

Analysis of Deaths from Carcinoma.—As indicated in table 5, 32 (46%) of the 70 known deaths, as of Dec. 13, 1956, were caused by carcinoma and 25 (78.1%) by gastrointestinal cancer. Deaths from carcinoma of the colon accounted for 16 (50%) of the total deaths from cancer in various sites, a very high rate. A higher rate of deaths from carcinoma occurred among patients with original diagnoses of multiple polyps than among those with single polyps: 8 patients (9%) of the 87 with multiple polyps died, whereas 24 (5%) of the 460 patients with original diagnoses of single polyps died.

For 13 of the 32 patients the diagnosis of carcinoma was made at the time of the original examination; 19 had no carcinoma at this time but later died of it. The distribution of deaths from carcinoma in terms of its presence or absence at the time of the original examination was as follows: Of 24 with single polyps, 9 did and 15 did not have carcinomas; of 8 with multiple polyps 4 did and 4 did not have carcinoma.

TABLE 3.—*Comparison of Original and Subsequent Pathological Diagnoses of Polyps*

* In cases where more than one subsequent polyp was found only the most significant pathological diagnosis was recorded.

To determine the incidence of subsequent carcinoma a detailed analysis was made of the 372 patients who were examined four or more years after the original diagnoses. Among the 311 patients originally diagnosed as having single polyps 10 (3.2%) were subsequently found to have carcinomatous polyps and/or associated carcinoma of the colon; among the 61 patients with multiple polyps originally 2 (3.3%) were subsequently found to have carcinomatous polyps and/or associated carcinoma of the colon. The incidence of subsequent carcinoma in the total 372 patients with single and multiple polyps was 3.2%, significantly lower than the 13% in the original group of 537 patients examined at the beginning of the study. The decrease may reflect the beneficial effect of prompt removal of the premalignant lesion. If adenocarcinomatous polyps are included, the incidence of subsequent malignancy was 6.7%, far below the corresponding figure of 32.2% noted on the original examination and again suggesting the possible beneficial effect of early removal of polyps.

Only five deaths from carcinoma of the colon had occurred four to nine years after an original examination showed no evidence of carcinoma. On the basis of the original group of 467 patients without carcinoma, this incidence is 1.1%. This figure can be compared to the 11 deaths occurring four to nine years later among the 70 patients who did have carcinoma at the time of the original examination, as either a carcinomatous polyp or an associated colonic carcinoma, an incidence of 15.7%. (It is only a coincidence that there were 70 original carcinoma cases and a total of 70 deaths in patients in the study.)

Patients Whose Polyps Manifested Adenocarcinomatous Change

Follow-up data are available on 56 patients with polyps originally diagnosed as adenocarcinoma (carcinoma in situ or adenocarcinoma grade 1). Thirty-two (57.1%) had no subsequent polyp formation; 19 of the 28 with single polyps had been treated by local biopsy only and 9 by simple surgical excision. Twenty-four patients (42.9%) subsequently developed polyps; 8 were adenocarcinomatous or frankly carcinomatous polyps, and these merit further description.

CASE 1.—A 55-year-old woman had a large fungating mass, diagnosed as adenomatous rectal papilloma, probably carcinoma, which was removed by biopsy snare at a level 17 cm. above the anal ring. Two weeks after this an adenocarcinomatous polyp was removed at the same level, again by biopsy snare at proctoscopy. Three years after this removal the patient underwent an anterior resection of the sigmoid colon for adenocarcinoma, with an end-to-end anastomosis. Two years postoperatively, results of proctosigmoidoscopic examination were negative. Three years later the patient reported that she remained in good health.

TABLE 4.—*Original Pathological Diagnoses*

	Single Polyps	Multiple Polyps
Benign and questionable	325	60
Carcinomatous	19	12
Adenocarcinomatous	88	15
No diagnosis	18	0
Total	450	87
Associated carcinoma of colon	33	6

CASE 2.—A 39-year-old woman had three polyps, from 1 to 2 cm. above the anal ring, which were removed by minor surgery. These were diagnosed as adenomatous, adenocarcinomatous, and adenomatous hyperplastic, respectively. Two years postoperatively two polyps were removed locally from the 5-cm. level and were diagnosed as hyperplastic rectal mucosa. After another two years the patient again developed numerous small polyps, located immediately inside the anal ring in a hypertrophied, friable mucosa. A surgical transanal partial excision was performed. Seven months after this, proctosigmoidoscopy revealed a sessile polyp; this was removed by local surgery, and the diagnosis again was adenocarcinoma. The next year the patient was found to have a plaque-like area of adenocarcinoma just inside the anal ring; this area was fulgurated. Examinations two and three years subsequently (six and seven years, respectively, after the original diagnosis) showed no further disease.

CASE 3.—A 56-year-old woman had an adenocarcinomatous polyp at the splenic flexure, which was excised. Two years postoperatively the patient developed another adenocarcinoma at the 13-cm. level, which was excised locally. In the third year of follow-up study the patient underwent a sigmoid polypectomy for an adenocarcinomatous polyp. In the fourth year a polyp, diagnosed as a hyperplastic mucosal nodule, was found at the 11-cm. level. The examination showed no further disease in the fifth year, but in the sixth year a polyp was discovered in the hepatic flexure; this has not yet been removed.

CASE 4.—A 66-year-old man had an adenocarcinomatous polyp just within the anal ring, which was removed. The next year the patient had another adenocarcinoma in a similar area. In the second year of follow-up study the patient was noted to have a similar lesion in the same location; 10 months later a fungoid mass was found on the anterior wall just inside the anus and excised. The pathological diagnosis was adenocarcinoma. In the fourth year a combined abdominal-perineal resection was performed because of carcinoma. In the fifth year an adenocarcinomatous polyp was excised from the colostomy site. The x-rays at the sixth, seventh, eighth, and ninth year follow-up examinations showed no further disease.

CASE 5.—A 50-year-old man had three polyps at the sigmoid colon, which were removed by transabdominal incision. Two of these were diagnosed as adenocarcinoma, the other as a benign adenoma. In the third year a hyperplastic rectosigmoid polyp at the 13-cm. level was removed, and another polyp was seen in the proximal descending colon. Two polyps at the descending colon were excised by abdominal incision at the fourth-year follow-up examination. These were diagnosed as preinvasive carcinoma in a large polypoid adenoma and a small benign polyp, respectively.

CASE 6.—A 64-year-old man had a 5-mm. sessile polyp, diagnosed as adenocarcinoma, which was removed at the 13-cm. level. A biopsy was done on an irregular polypoid mass at the 7-cm. level. A diagnosis of malignant papillary adenomatosis of the rectum was made, and this lesion was removed surgically. In the second year of follow-up study a similar area was found at the 7-cm. level and diagnosed as adenocarcinoma; the lesion was cauterized by a local physician. During the fourth year of follow-up study a plaque of polypoid nodules was seen in the same area and a biopsy was done. The diagnosis was adenomatous polyp, possibly malignant. The patient refused the recommended surgical resection.

CASE 7.—A 59-year-old woman had a papillary adenocarcinomatous polyp, at the 8-cm. level, which was removed. Three subsequent proctosigmoidoscopies showed no further disease, but the fourth, performed seven months after the original polyp was found, revealed a 3-cm. polyp at the 7-cm. level. Biopsies indicated an adenocarcinomatous polyp, which was removed by surgical local excision. No polyps were discovered during four subsequent years of follow-up examinations.

TABLE 5.—*Analysis of Deaths in Patients Studied*

	Deaths, No.	% of Total Deaths	% of Total Carcinoma	% of Total Gastro-Intestinal Carcinoma
Total Deaths	70	100.0	...	...
Noncarcinoma	38	54.3	...	...
Carcinoma	32	45.7	100.0	...
Nongastrointestinal ..	7	10.0	21.9	...
Gastrointestinal	25	35.7	78.1	100.0
Colon	16	22.8	50.0	64.0
Other Sites	9	12.8	28.1	36.0

CASE 8.—A 57-year-old man had a 1.5-cm. polyp on a small stalk at the 8-cm. level, which was removed by cautery. The pathological diagnosis was adenocarcinoma. Biopsy of friable granular mucosa one and one-half years later demonstrated adeno-

carcinoma. One year later, although proctosigmoidoscopy showed no disease, a barium enema revealed a polyp of the sigmoid colon. A segmental resection of the sigmoid colon with primary end-to-end anastomosis was performed. Careful examination of the resected specimen revealed two polyps, one an adenocarcinoma and the other a benign adenomatous polyp. Repeated examinations, including x-ray and proctosigmoidoscopy, during the next three and one-half years showed no further disease (seven and one-half years of follow-up examination).

The course of these eight cases indicates the importance of repeated examinations at regular intervals. Death from a subsequent carcinoma may be prevented after proper local excision or fulguration of the lesions and early surgical resection. Patients with polyps originally diagnosed as adenocarcinomas do not appear more likely to develop subsequent polyps than any other group of patients with polyps. Only eight (14.3%) of these patients in whom adequate follow-up study was available developed additional malignant polyps and/or carcinoma. This figure is significantly lower than the 32.2% incidence of malignant polyps, carcinoma, and associated colonic carcinoma found at the original examination of the 537 patients with polyps. On the other hand this figure far exceeds the over-all incidence of malignant polyps and carcinoma noted in the total group of 9,669 patients (3.3%). Thus, patients with polyps appear more prone to develop malignant lesions in the colon and rectum than does the "average gostrointestinal patient."

Roles of X-ray Examination and Proctosigmoidoscopy in Early Discovery of Rectal and Colonic Neoplasms.—In our original study[1] 92.5% of the cases of patients with polyps were diagnosed by proctosigmoidoscopy, whereas x-ray examination accounted for 7.5%. On subsequent follow-up examinations, however, the number of cases diagnosed by x-ray examination alone increased substantially to 27.3%, probably as a result of the more frequent use of air contrast studies and the more careful examinations in these selected cases, stimulated by the knowledge that the patients were prone to develop polyps. Thus, while both procedures are indispensable, the results obtained by proctosigmoidoscopy are the more rewarding.

Comment

In a six-year period 9,669 proctosigmoidoscopic and x-ray examinations resulted in the detection of polyps in 537 patients. A vigorous follow-up program from four to nine years later yielded the following important information: At one time or another, 92.7% of the patients returned for examinations. Of the original group of 537 patients 372 were reexamined in the four-year to nine-year study; 41% of these developed new polyps. The rate of new polyp formation did not vary greatly during each year of study, ranging from 9.3 to 15.9%, but it was higher than usual, indicating that members of the group were "polyp-prone."

The incidence of carcinoma of the colon in patients without polyps was 2.1%. The original incidence of carcinomatous polyps in the 537 patients was 5.8%. An additional 7.2% had associated carcinoma of the colon; thus, 13% had carcinoma either in the polyp or in other sites. If the cases of carcinoma in situ (adenocarcinoma) are added to this figure, then the percentage of patients with polyps with evidence of malignancy is 32.2.

The incidence of subsequent carcinoma in the 372 patients was 3.2%, considerably below the incidence found at the beginning of the study. This decrease may reflect the preventive effect of prompt removal of a premalignant lesion. During the course of this study 70 patients died, 32 from carcinoma and, of these, 16 from cancer of the colon.

Local treatment, i. e., removal by biopsy or snare, with fulguration of the base, appears to be adequate in dealing with the histologically benign polyp within reach of the proctosigmoidoscope. Large polyps in the rectum or colon should be removed surgically. Polyps with focal areas of carcinoma, but without invasion of the stalk (adenocarcinoma grade 1 and carcinoma in situ), may be treated in the same manner as benign polyps, with frequent reexamination of the rectum and colon by proctosigmoidoscopy and barium enema. If invasion of malignant cells is demonstrated in the stalk of a pedunculated polyp or in the intestinal wall, the preferred treatment is that required for carcinoma.

Although there is probably great biological variability in the behavior of polyps, there is no direct evidence in this long-term study that all polyps are progressive lesions, eventually becoming cancerous, or that all carcinomas originate as benign polyps. Occasionally, early carcinoma or carcinoma in situ may be detected in a grossly benign polyp. Since there is no decisive clinical method of predicting the behavior or the pathology of the individual polyp, such lesions should be removed. The patient with polyps is prone to develop additional polyps and also carcinoma of the rectum or colon at other sites. The incidence of carcinoma of the colon in 9,132 patients without polyps was approximately 2%. In the 537 patients with polyps in the present study, the incidence of carcinoma in the polyps was 5.8%. The total incidence of carcinoma including associated carcinoma in other sites in the colon and excluding adenocarcinoma was 13%.

The results of these studies indicate that the individual colonic polyp, unless it is an obvious carcinoma, can be treated adequately by local fulguration or total removal by biopsy with no danger of local recurrence. The presence of a polyp is a signal, however, indicating an abnormal colonic mucosa prone to develop either new polyps with varying degrees of malignancy or carcinoma. Because of the predicted high rate of new polyp formation in patients prone to develop polyps, it is impossible on the basis of this study to determine when yearly reexamination is no longer necessary. However, the present analysis suggests that it is reasonably safe to discontinue such examinations after they have shown no further disease for five consecutive years.

Summary and Conclusions

The presence of a polyp in the colon or rectum is an indication of an abnormal mucosa prone to develop new polyps, benign or malignant. New polyps developed in approximately 40% of patients with polyps of the colon and rectum observed for from four to nine years. The yearly new polyp formation rate, approximating 10%, indicated a group of patients prone to develop polyps and requiring frequent reexamination.

The incidence of carcinoma of the colon was twice as high in patients with multiple polyps as in those with single polyps; the lowered incidence of subsequent carcinoma of the colon suggests the beneficial effects of early diagnosis and removal of polyps. Local removal appeared to be adequate treatment for benign polyps and for adenocarcinoma within reach of the proctosigmoidoscope. Patients with polyps should be examined annually until findings of at least five consecutive yearly proctosigmoidoscopic and roentgenologic examinations of the rectum and colon have been negative.

950 E. 59th St. (37) (Dr. Kirsner).

This investigation was supported in part by a grant from the National Cancer Institute of the National Institutes of Health, U. S. Public Health Service.

Dr. Paul C. Hodges, Chairman Emeritus of the Department of Radiology, and his staff interpreted the roentgenograms for this study.

STAPHYLOCOCCIC PNEUMONIA

Capt. Shakeeb Ede, Capt. George M. Davis
and
Capt. Francis H. Holmes, (MC), U. S. N.

The assumption that staphylococci have gained in importance among the causes of pneumonia is questioned. The comparison here made between statistics published before 1932 and the data assembled by the authors from 1,177 cases of acute pneumonia indicate a decline. But when staphylococcic pneumonia does occur it develops rapidly, the patient is liable to show sudden intensification of dyspnea and cyanosis, and serious complications are likely. Diagnosis depends on the bacteriologist, and treatment consists primarily of using the proper antibiotic. The disk-sensitivity method for determining the antibiotic has been practical and useful. Among the antibiotics tried by the authors, chloramphenicol with erythromycin and novobiocin with erythromycin have seemed to be the most reliable. Symptomatic medication is also necessary. When complications like pyopneumothorax, empyema, or progressive pleural effusions appear, early surgical intervention is advised, and close cooperation between surgeon and internist should be maintained.

Currently, one of the problems facing medicine is the apparent pandemic of staphylococcic infections. Almost every hospital has been alerted to or faced with the immediate problem of dealing with a seeming increase in staphylococcic infections. The literature on this subject is accumulating rapidly. Investigators in the field of antibiotic research and development continue to search diligently for the drug that will effectively and safely destroy the staphylococcus. Accredited hospitals have active committees on infections. Hospital staffs are encouraged to put aside one or more of the effective antistaphylococcic agents for special treatment of the more serious staphylococcic infections in order that, in case of an epidemic, "all of the eggs won't be in one basket." Some surgical technicians, assured by the availability of many broad-spectrum antibiotics, became a bit careless after 1940 and their techniques became less strict. However, with the increase in staphylococcic infections, surgical masks have again been pulled over the nose, visitors to the surgical suites have been more carefully screened and cautioned, nursery personnel have been more frequently examined, and many physicians have become more reluctant to prescribe antibiotics when indications are not clear. The

---

From the U. S. Naval Hospital, Great Lakes, Ill.

question of the place of the staphylococcic pneumonias in this problem stimulated our group to this investigation.

After the sulfonamides became available, the majority of physicians became increasingly less concerned about cases of pneumonia. With the many effective antibiotics available, the oft-repeated phrase, "If pneumonia is present, I can cure that" seemingly was true. However, on occasions, this supreme confidence in the power of the antibiotics became shaken when a patient with a fulminating staphylococcic pneumonia failed to respond. Intensive search for the causative organism with particular reference to types of pneumococci responsible has given way now to such questions as "Is this a staphylococcic pneumonia?" and "Is it sensitive to an antibiotic?"

Many physicians are reviewing their knowledge about pneumonias. There is concern over whether a new type of pneumonia has developed more or less as the result of the use or the abuse of antibiotics. However, an excellent description was given by Reimann [1] in 1933 with references to similar good descriptions by Chickering and Park,[2] Netter,[3] Leichtenstern,[4] and others long before, indicating that perhaps we have just forgotten sound previous knowledge and need only to refamiliarize ourselves with a problem that was apparent before the word antibiotic was ever used.

Is the incidence of staphylococcic pneumonia really increasing? If so, perhaps we would be justified in assuming that the abuse of antibiotics may be a factor. Cole [5] reported on a series of 211 acute pulmonary infections from 1927 to 1928, stating that 9% were due to or associated with staphylococcus. Habbe [6] in 1929 called attention to the relatively high incidence of this organism found at autopsy in 270 cases of fatal acute pneumonia. Lyon, in 1922, felt that the staphylococcus was an important etiological agent (9.6%) in the acute pneumonias seen in children. Menten and associates [7] presented sound evidence that staphylococcic pneumonia was definitely a serious problem long before antibiotics were made available.

Results of Present Study

At the U. S. Naval Hospital, Great Lakes, Ill., from 1957 to 1958, there were 11,112 admissions. Of this group, there were 1,177 patients (10%) with acute pneumonia. Eighteen of these cases (1.5%) were of staphylococcic etiology. From 1956 to 1957, there were 477 (4.4%) cases of acute pneumonia in a total of 10,931 admissions. Seven of these (1.5%) were proved to be of staphylococcic etiology. The higher percentage of acute pneumonias in the 1957-1958 period was directly correlated to the influenza epidemic during this time.

From those that occurred during the past three years, 36 cases of staphylococcic pneumonia were analyzed. To determine how many patients of this group required some type of operation, the following complications and procedures were reviewed: death, 1; bilateral pyopneumothorax, 1; unilateral pyopneumothorax, 8; pleural effusion, 8; empyema, 10; lung abscess, 3; pericarditis, 1; shift and fixation of the mediastinum, 1; pneumatocele, 1; atelectasis, 2; thoracentesis (single or multiple), 16; thoracotomy with closed tube drainage, 15; partial lobectomy, 1; and decortication, 3.

While the follow-up period is still too short to evaluate distant complications, such as bronchiectasis, emphysema, or pulmonary fibrosis, to date only one case has shown residual bronchiectasis and we have been impressed with the ability of the pulmonary structures to effectively and apparently completely recuperate once the acute process is controlled. It is further believed that, quite possibly, the three decortication procedures might well have been avoided had surgical intervention been more prompt.

In these 36 cases collected since 1956, the only death occurred within 72 hours of the initiation of the patient's symptoms. Attention is directed to the fact that 34 of these cases were of primary pneumonia, apparently incurred outside the hospital in the same manner that bronchopneumonia or pneumococcic pneumonia is contracted. Two of the cases were of secondary pneumonia, one secondary to osteomyelitis and one secondary to a carbuncle on the neck. Each of these patients had a positive blood culture. None of those with primary pneumonia had positive blood cultures. It is considered most important to realize that most of these cases were not due to a "hospital organism." Four cases may have been due to a hospital organism in that two of the infants observed were children of staff physicians; the mother of one patient worked in the nursery and her throat culture showed coagulase-positive Staphylococcus aureus in almost pure culture, and one patient contracted his disease while under observation in a surgical ward. In each of these instances, the pneumonias were more severe, the complications more rapid, and the drug control more difficult. This has been our experience with the secondary infections arising immediately or shortly after surgical procedures. These seem to be hardier organisms, less amenable to medical therapy, and they give higher morbidity and mortality. Consequently, hospital organisms are to be feared.

All patients admitted had x-ray evidence of pneumonia, and the specific bacteriological agent responsible was determined by throat or sputum cultures or, whenever possible, blood or pleural fluid cultures. Certain of these cases were quite benign, did not clinically seem like the type of infection we fear, and responded relatively dramatically to various antibiotics. These might be classified with another type of acute pneumonitis wherein the throat and sputum cultures yield a high incidence of coagulase-positive Staph. aureus as an incidental finding. Yet, in each case, the organism was highly predominant in throat or sputum cultures and was sensitive to the antibiotic used by test; consequently, these cases were included. In each patient in whom a complication occurred, coagulase-positive Staph. aureus was cultured from the pleural fluid, empyema fluid, or abscess. Thus, it would seem that there has really been no increase in the problem but rather a reawakening that there has always been a problem.

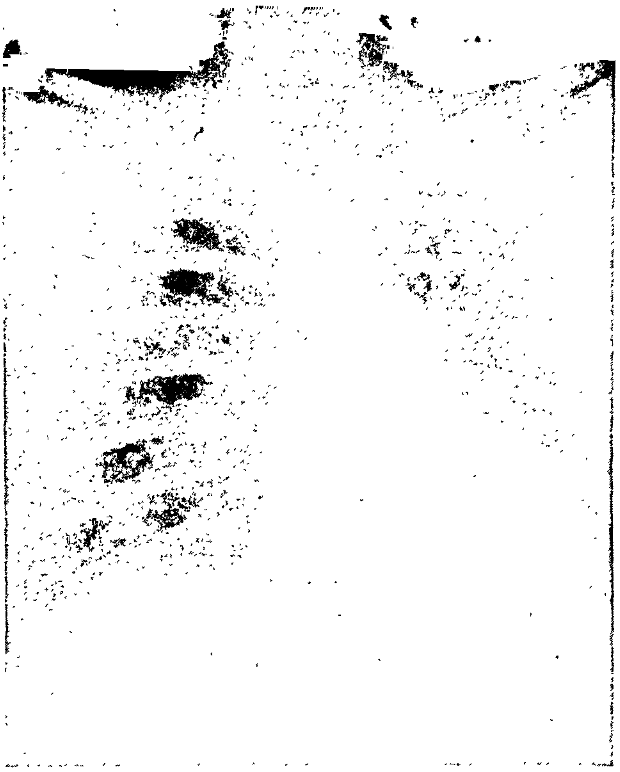

Fig. 1.—Roentgenogram of patient with staphylococcic pneumonia, showing minimal involvement during first 24-48 hours.

Predisposing Factors

The predisposing factors present in staphylococcic pneumonia were ably and frequently described by many competent observers long before antibiotics came into common use. Those that have impressed us are as follows: 1. An upper respiratory infection or influenza syndrome ushers in or is present immediately prior to the staphylococcic pneumonia. 2. Children, and particularly infants, seem more susceptible to the more fulminating forms of this type of pneumonia. As might be expected, patients with fibrocystic disease are reported to be highly susceptible and, when the complication of staphylococcic pneumonia is superimposed, it is quite likely to end fatally. 3. A focal infection, such as staphylococcic cellulitis, carbuncle, or osteomyelitis, may result in bacteremia with multiple lung implants and serious pneumonia. 4. Debilitated patients and defective children seem more disposed to develop staphylococcic pneumonia. Anal sis of the histories of our patients has shown litt to substantiate the feeling that the abuse of ant biotics has contributed to the incidence of th type of pneumonia to date.

What characterizes the patient with acute pne monia due to staphylococcus? On the whole, the is nothing short of bacteriological proof that de nitely identifies the disease clinically. Yet, certa signs, symptoms, or findings should alert the clin cian to this possibility. Again, it is emphasized th many excellent reviews have described these fin ings. Those that seem significant to us are as fo lows: 1. The presence of a dyspnea out of propo tion to the clinical findings of pneumonia. 2. In th more virulent forms, a dusky cyanosis of the li and nailbeds with the dyspnea. 3. The x-ray of th chest giving normal findings or showing minim involvement for the first 24 to 48 hours (fig. 4. X-ray finding of multiple lobe involvement scattered pneumonic areas within both lung fiel (fig. 2). 5. In the patient showing toxic reaction an obviously ill, pleural pain particularly associate with a rapid or progressive pleural effusion whi is not responding to the usual antibiotics. In 19 any patient who develops an empyema seconda to any acute pneumonia may have a staphylococc infection. 6. The entire hemithorax becoming ra idly involved (*this is almost invariably staphyloco cic in origin, particularly in an infant*). 7. Th development of pyopneumothorax or a bronch pleural fistula during the course of acute pneum nia. This virtually is an assurance of staphylococcu origin. This must be most carefully watched for an its development rapidly diagnosed and treated Often the patient, though acutely ill, is seemingl holding his own and then suddenly shows eve

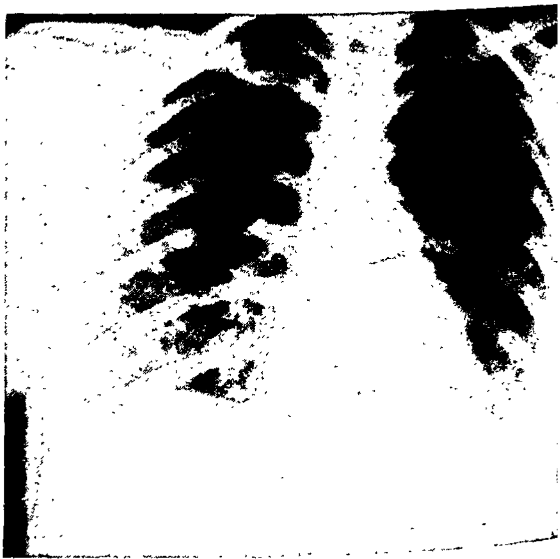

Fig. 2.—Roentgenogram showing multiple lobe involv ment.

more marked dyspnea, cyanosis, and even shock. Frequently, pleural pain heralds this; there may be progressive effusion prior to the pneumothorax and the clinician may become impressed with the amphoric quality of the breath sounds as tension builds up in the involved area prior to the perforation of the pleura. Pyopneumothorax may develop within one to four days after onset of illness in an infant or child. 8. Pneumatocele developing during the course of the acute pneumonia (fig. 3). 9. Any acute pneumonia with which pleural effusion or, certainly, empyema has developed (fig. 4).

Diagnosis

The roentgenologist is invaluable in diagnosis and follow-up study of patients with more serious staphylococcic pneumonia. Probably the first indication the roentgenologist has that a pneumonia is staphylococcic comes from the clinician who states his patient shows a greater toxic reaction than the x-ray findings would indicate. At least three of the present series of patients with pneumonia had negative findings on initial chest roentgenograms, although they were obviously in respiratory distress and acutely ill at the time of admission. Changes are rapid in staphylococcic pneumonia, and often a second chest x-ray taken within 24 hours will show rather extensive findings. As pointed out by Rigler in 1933,[8] without clinical correlation, the appearance of a typical staphylococcic pneumonia is almost identical with that of a *resolving* lobar *pneumonia* or bronchopneumonia. The most common x-ray finding on admission in the patients of this series was several small, roughly oval or rounded areas of consolidation, quite often bilateral. Change in the appearance is again the rule, and clearing of many of the original foci may be observed. Concurrent with this clearing will be the appearance of new foci either in the same lobes or in hitherto uninvolved lobes.

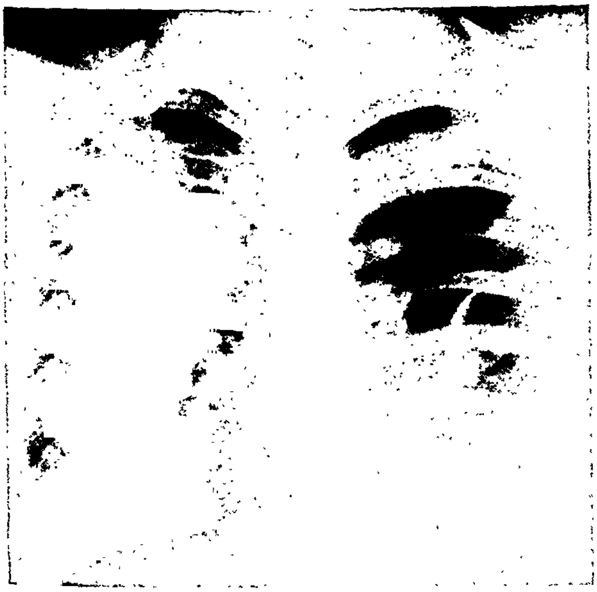

Fig. 3.—X-ray appearance of pneumatocele secondary to staphylococcic pneumonia.

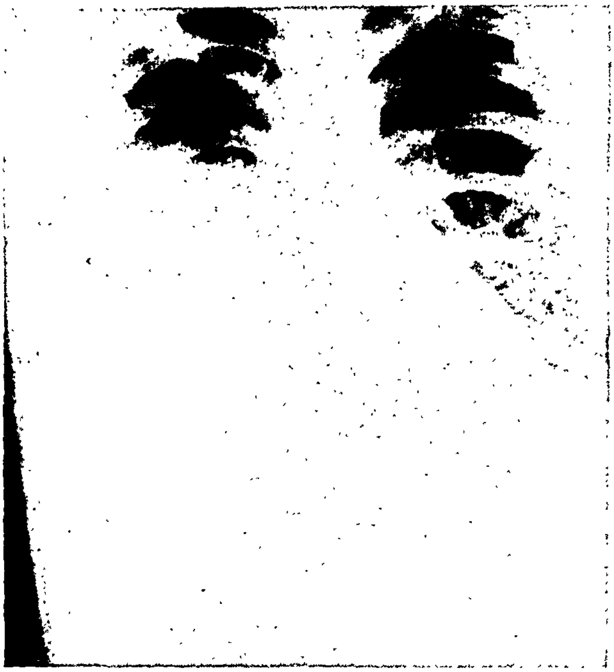

Fig. 4.—X-ray appearance of empyema as complication of staphylococcic pneumonia.

Infiltrates that persist will usually demonstrate cavity formation within 96 hours (fig. 5). Special overpenetrated films may be necessary to demonstrate the early cavitation. After cavitation, any of six courses may develop: (1) spontaneous resolution of a cavity, (2) coalescing of small cavities to form larger cavities, (3) evacuation of the fluid content and persistence of the cavity as a pneumatocele, (4) bronchopleural fistula formation (pyopneumothorax), (5) empyema formation without bronchopleural fistula, and (6) necrosis of affected lungs. The coalescing of small cavities is practically pathognomonic of staphylococcic pneumonia.

In connection with bronchopleural formation or pyopneumothorax, it is felt that this is always heralded by pleural irritation and the attendant formation of fluid. Fluid formation is a sign to which the clinician should be alerted immediately, as it is a forewarning that a crisis in the management of the patient should be expected. With this sign the surgeon promptly is notified, in the event that bronchopleural fistulation may occur and may be attended by mediastinal shift and collapse of enough lung so that closed drainage may be lifesaving.

Medical Treatment

The medical treatment of this serious disease consists primarily of using the proper antibiotic. Along this line of endeavor, certain things have been quite valuable to us:

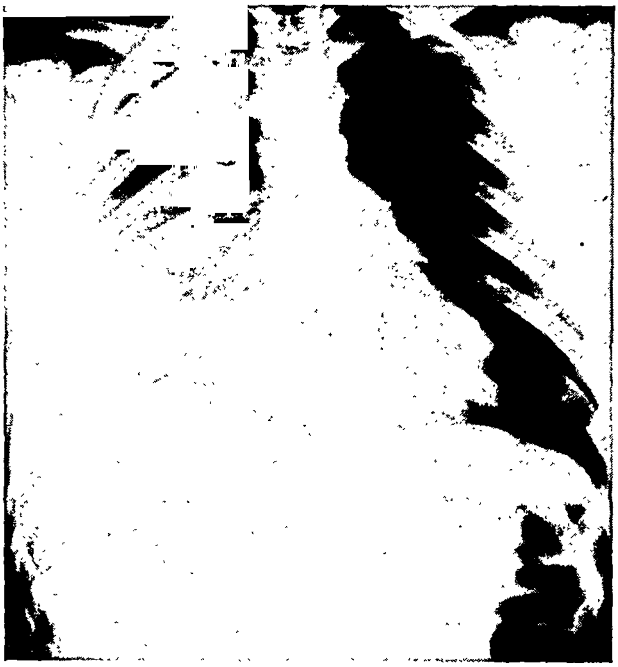

Fig. 5.—X-ray evidence of lung infiltration which has persisted to cavity formation.

First, the disk-sensitivity method of determining the appropriate antibiotic, available in most laboratories, has been practical and useful. Admittedly, it is not as accurate as the tube-dilution method; however, it is more rapid and more commonly available.

Second, some of these infections will respond quite satisfactorily to average doses of penicillin and/or tetracyclines. However, in the acutely ill patient with an unusual amount of dyspnea and toxicity, these two drugs may be totally ineffective, and, if they are relied on too long, the patient may die.

Third, chloramphenicol (Chloromycetin) with erythromycin and novobiocin with erythromycin have seemed to be our most reliable combinations. Full therapeutic doses are required. Often the use of all three has been effective. Continuation of therapy for 7 to 10 days after apparent recovery is advisable.

Fourth, ristocetin, kanamycin, and massive doses of penicillin have been used an insufficient number of times by our group to state their true value.

Fifth, oxygen, salicylates, anodynes, cough mixtures, and sedatives have been used as required symptomatically. Blood transfusions have been required in a few cases in which anemia seemed to contribute to slow convalescence. Gamma globulin has been used in critically ill patients, but its real efficacy could not be judged because of the variety of other agents being given at the same time. In patients in whom pleural pain was severe and agonizing, our anesthesiology department was singularly successful in giving marked relief by regional blocks with procaine derivatives. Steroids were used with apparent good results for a short time in one patient with overwhelming toxemia.

Surgical Treatment

Before a discussion of the surgical treatment of this disease is undertaken, it is well to recall that Staph. aureus has been believed to produce potent enzymes (hyaluronidase, proteinase, and coagulase) and toxins (hemolytic toxin, leukocidin, and necrotoxin; *alpha, alpha prime,* and *beta toxins* have also been described).

A fibrinolysin (staphylokinase) has also been found. One of the questions not infrequently puzzling to the clinician is, "Even if my antibiotic reaches and kills the organism, will the purulent material remaining, though bacteriologically sterile, continue to offend my patient?" In certain of our patients we have apparently achieved bacteriologically sterile cultures (blood, serous fluids, throat, and sputum), yet coalescing of abscesses, perforation of the pleura, and persistent fever has continued. Possibly the remaining toxin, e. g., the necrotoxin, remains active though the organism has been killed or is no longer reproducing. This concept lends support and logic to early surgical treatment of the complications.

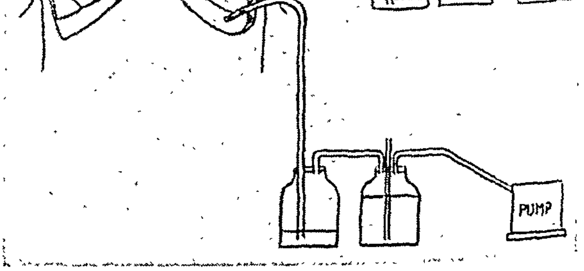

Fig. 6.—Diagram of underwater suction used in this series of cases.

The complications occurring within the thorax during the course of the pneumonia are pleural effusion, empyema, pneumatocele, atelectasis, lung abscess, pyopneumothorax or bronchopleural fistulation, pericarditis and mediastinal shift with pulmonary embarrassment and/or with fixation of the mediastinum in other than its proper anatomic position.

In the patient who died within 72 hours after initiation of symptoms, postmortem examination of the lungs revealed the characteristic process. The lungs were completely riddled by multiple small abscesses. Some of these were in the process of burrowing and coalescing to form larger abscesses. Little intervening lung remained for ventilation, and the patient literally suffocated.

A summary of some of our surgical recommendations is as follows: 1. The prompt placement of a closed drainage tube attached to suction equipment in a patient with developing pyopneumothorax or bronchopleural fistula may be lifesaving. Certainly, it will decrease morbidity. 2. Early thoracentesis in a pleural effusion is of great diagnostic value. If the patient is not improving, it is our belief that, often, the introduction of closed drainage for 24 to 48 hours (since the tube will likely remain closed after this) may result in a prompt improvement in the clinical condition of the patient. We have not seen any complications from this form of therapy, have found it safe and well tolerated by the patients, and believe that it may have prevented progression of the disease and the necessity for decortication procedure later. Repeated thoracentesis is to be avoided. When the patient is not definitely improving and fluid is present and has been shown on culture to contain pathogenic staphylococci, we favor early closed-tube drainage in preference to repeated thoracenteses, even if the fluid is not empyematous in appearance. 3. Certainly, prompt drainage of empyema is indicated. Delay in this with reliance on repeated thoracentesis results in loculation of fluid difficult to find, in long morbidity for the patient, and in almost certain necessity for eventual decortication. 4. As a rule, pneumatoceles are left alone; many have been seen to completely disappear after several months' follow-up study.

The technique for closed drainage with suction as employed by our group is as follows: With the patient in bed and under local anesthesia, an incision about 1 in. long is made in the skin of the chest wall in the intercostal space overlying the area involved. The incision is continued through the subcutaneous tissue, fascia, and muscle layer to the intercostal muscle. An anesthetist may give oxygen under positive pressure to prevent collapse of the involved lung when the pleural cavity is entered. A 32 F. catheter is then inserted through the intercostal muscle with a large, blunt hemostat. Occasionally, a small catheter is necessary in an infant, but, by compression of the end of the catheter with the hemostat, large catheters can be safely passed between the ribs. Reliance on small catheters has been unsuccessful in our experience because they will not remain open a sufficient length of time. The catheter is secured adequately and connected to underwater seal and suction (fig. 6). The wound is closed in layers and dressing applied. Change of catheters as necessary to prevent collapse, empyema, or mediastinal shift is performed.

Summary

An attempt to correlate the incidence of primary staphylococcic pneumonia with the use of antibiotics revealed that the incidence is apparently no greater now than prior to the development of antibiotics. Thirty-four cases of primary staphylococcic pneumonia and two cases of secondary staphylococcic pneumonia observed at the U. S. Naval Hospital, Great Lakes, Ill., since 1955, were included in the study. Chloramphenicol (Chloromycetin) plus erythromycin, novobiocin plus erythromycin, or a combination of all three seemed to give the most favorable results in the medical management of the disease. A high incidence of complication was seen with this form of pneumonia.

Close cooperation between the surgeon and internist should be maintained, and early surgical intervention is advisable when complications arise. The prompt institution of closed tube drainage with use of a large catheter (30 to 32 F.) for pyopneumothorax, empyema, and progressive pleural effusions has been instrumental in saving lives and reducing morbidity.

FECAL IMPACTION IN MODERN PRACTICE

Karl-Albert Dresen, M.D.
and
Guy L. Kratzer, M.D., Allentown, Pa.

An increasingly large number of patients suffer from the various manifestations of fecal impaction. Proper management of the condition will prevent much suffering, many laparotomies, and even colostomies. Fecal impaction is defined as the presence in the rectum or colon of firm stercus which can be dislodged only with the aid of the finger, enemas, or operation. Organic causes include obstructing lesions, anal fissure, and diseases such as magacolon, general paresis, and infantile paralysis. Fecal impaction occurs at any age and can mimic other diseases by producing symptoms suggesting diarrhea, tumor, or urinary calculi. Physical examination may reveal a hard fecal mass in the rectum, a hard, putty-like mass at the end of the sigmoidoscope, distended abdomen, or palpable hard lumps in the abdomen. Impacted scybala in the lower part of the sigmoid may be dislodged by pelvic, abdominal, or sigmoidoscopic manipulation. Colonic irrigation is a pertinent form of therapy for suspected impactions higher in the colon. Two typical case histories are presented.

Experience has shown that some physicians do not regard fecal impaction as a common clinical entity with serious potentialities. Our data are obtained from a study of 500 consecutive patients suffering from fecal impaction. The problem is analogous to appendicitis or urinary obstruction and similarly requires prompt diagnosis and treatment. Proper management of fecal impaction will enhance the efforts of many who have pioneered in the prevention of unnecessary surgery. Much suffering, many laparotomies, and even colostomies may be avoided.

Information relating to this subject in the textbooks is incomplete. The common problems which plague patients must be considered. Physicians must be willing to examine and give the benefit of their experience to their patients. Problems of diagnosis cannot be delegated to the "other fellow"—the nurse or laboratory technician.

Constipation is a common ailment of mankind and since fecal impaction is a frequent sequela we believe that a didactic review substantiated with pertinent case histories and statistics is timely and imperative. The subject is important to both medical men and surgeons. If the surgeon fails to show sufficient awareness of this and other common ailments, those who believe that experience in general practice should be a requisite for specialty training have a point indeed.

Definition and Etiology

Definition.—Fecal impaction is defined as the presence of firm stool in the rectum or colon which can only be dislodged with the aid of the finger inserted in the rectum, with enemas, or with an operation. Its consistency may vary from putty-like to rock-like material. Although this is rare, we have seen fecaliths resembling billiard balls in both the small and large intestines causing intermittent intestinal obstruction and requiring operation for cure. Miniature fecaliths are frequently seen in the appendix and in diverticula (fig. 1).

The fecalith may consist simply of dehydrated stool or of a mixture containing other components, such as bulk laxatives, coriander seeds, drugs, or some other foreign body. Barium and bismuth have frequently been found in fecaliths.

In functional cases, fecal impaction causes an incomplete intestinal obstruction. In organic strictures of the intestine, fecal impaction may precipitate complete intestinal obstruction.

Etiology.—The causes of fecal impaction may be divided into functional and organic. Functional causes include dietary deficiencies, such as low-residue diet and insufficient food or liquids. The use of bulk laxatives, coriander seeds, or other foreign bodies in the diet may act as a nidus for the development of an impaction. Prolonged bed rest due to sickness or accident may be responsible. Patients taking large doses of antispasmodics have developed symptoms of intestinal obstruction and have been subjected to useless operations.

The organic causes include obstructing lesions, such as cancer, of the colon (fig. 2), rectum, and anus. Anal fissure or other similar painful diseases of the anorectal area may indirectly cause fecal impaction because the patient subconsciously delays bowel movement or incompletely empties the rectum and thus allows for the hardening of the stool over the course of days or months. The diseases, such as megacolon, paresis, and infantile paralysis, due to the nervous imbalance produce delayed emptying of the colon and, thereby, fecal impaction.

Resident in pathology (Dr. Dresen), and Chief, Proctology Department (Dr. Kratzer), Allentown Hospital.

Diagnosis and Treatment

Diagnosis.—Fecal impaction occurs at any age and can mimic other diseases by producing symptoms suggesting diarrhea, intestinal obstruction, tumors, megacolon, or urinary calculi. As in all diagnoses, the history is important. Oddly enough, patients with impaction in the rectum usually complain of diarrhea. This is usually because the impacted stool acts as a foreign body and the patient complains of frequent desire to empty the intestine. The impacted stool remains, but mucus, liquid stool, or even blood may be expelled at frequent intervals. The rectum may be so filled with stool that the patient does not have the strength to expel it completely but does expel a small amount each time. This is frequency from overflow. The situation is analogous to a distended bladder in which the patient voids at frequent intervals. The patient usually expels gas but cannot expel the offending stool. The patient may also complain of abdominal cramps and symptoms of complete or incomplete intestinal obstruction. The impacted stool may cause ulceration of the mucosa with massive hemorrhage. Physical examination may reveal a hard stool in the rectum, a hard, putty-like mass at the end of the sigmoidoscope, distended abdomen, or palpable hard lumps in the abdomen. A roentgenogram of the abdomen or a barium enema may be of help. One diagnostic help in digital or sigmoidoscopic examination is the fact that a fecal impaction usually can be dented with the finger or the scope. However, there are rare cases in which the fecalith is rock-like.

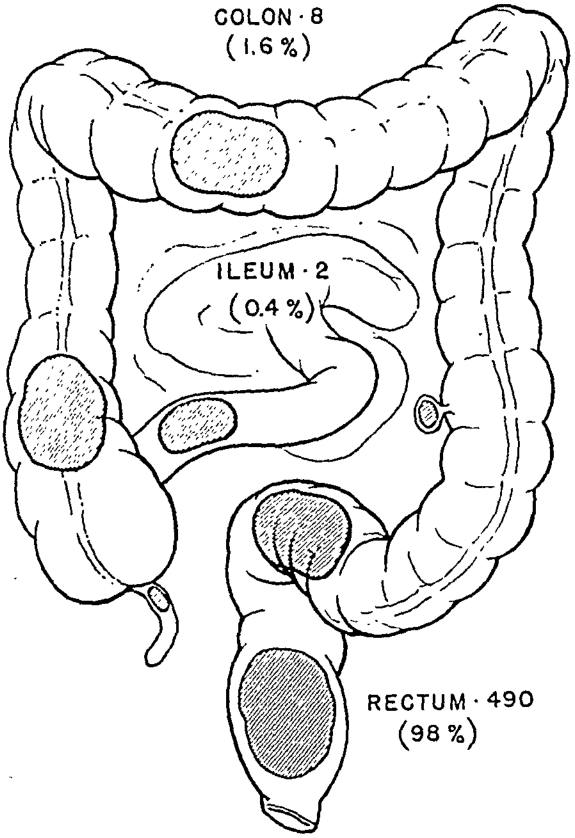

Fig. 1.—Location and frequency of fecal impactions.

Treatment.—Treatment is easy after the diagnosis is made. Impactions in the rectum can be broken or dislodged with the finger. Plain water enemas are helpful. Use of hydrogen peroxide has been discontinued because of the frequent sequela of proctitis. The patient should be in the knee-chest position, as water will not run uphill (fig. 3). Mineral oil instillations and enemas are used when the impaction is in the sigmoid or higher. The use of castor oil or similar laxatives by mouth in the presence of rock-like impacted stool in the rectum and colon is contraindicated because of the danger of precipitating complete obstruction, rupture of a diverticulum, or anorectal trauma. One must remember that in fecal impaction the intestine is partially obstructed and dilated. It is best to decompress it by means of enemas and continue this decompression for a number of days or until the intestine has regained its normal tone, after which an anticonstipation regimen with peristaltic stimulants may be used.

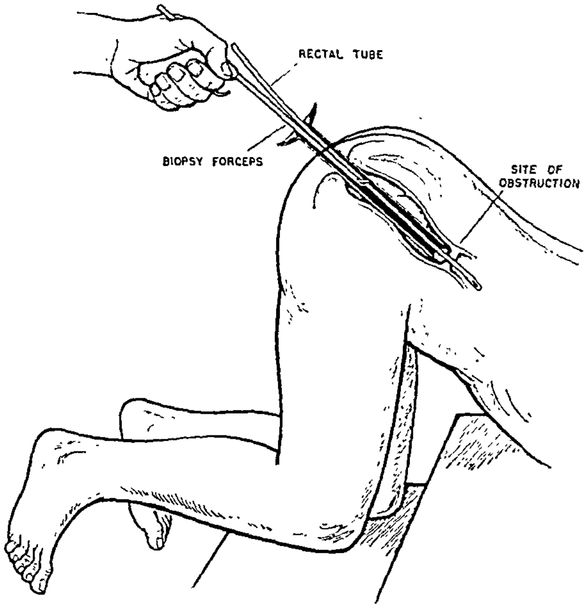

Fig. 2.—Method of inserting rectal tube beyond obstruction.

Fecal impactions in the lower part of the sigmoid may be dislodged by pelvic, abdominal, or sigmoidoscopic manipulation. For suspected impaction higher in the colon the colonic irrigation is a pertinent form of therapy, especially after an inconclusive barium enema or in the face of a poor surgical risk. The barium enema can always be repeated. The incidence of negative findings on exploration is high.

When impaction is associated with organic stricture of the anus, rectum, or colon, management must be modified accordingly. If the anus is contracted due to scar or other disease, it may be necessary to anesthetize the patient to enlarge the opening for proper examination and removal of the impaction. Frequently the anorectal pathology can be removed at the same time. This is particularly true in strictures and fissures. If the obstruction is at the rectosigmoid or higher and still within reach of the sigmoidoscope, a rectal tube can frequently be forced through the narrowed area and allowed to remain there until irrigations have allowed the imprisoned flatus and stool to escape, thus decompressing the colon and avoiding an emergency colostomy. Needless to say, one must be careful to avoid perforation of the colon. Good light and a long grasping forceps or wire mandrin are essential to the successful use of this maneuver.

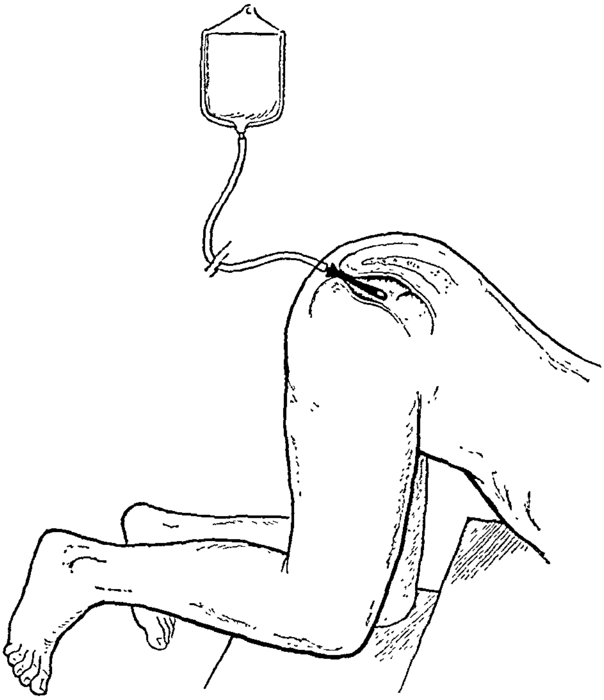

Fig. 3.—Knee-chest position for enema.

For organic strictures beyond the reach of the sigmoidoscope, surgical decompression is frequently necessary. However, colonic irrigations with the patient in the knee-chest position should be given a fair trial.

Report of Cases

Stimulus for this study was provided by an increasingly large number of patients suffering from the various manifestations of fecal impaction. Two illustrative case histories are accordingly summarized.

Case 1.—A man, aged 76, complained only of moderate constipation but sought medical care when a sudden massive amount of blood was expelled per rectum. Transfusion was necessary. Careful study, including sigmoidoscopy and x-ray of the colon, revealed only diverticulosis of the sigmoid colon. The patient was discharged but returned because of a fecal impaction in the rectum and recurrent hemorrhage. At laparotomy a large, partially obstructing mass was found at the ileocecal area. Hemicolectomy was performed, and the patient subsequently did well. The specimen showed a golf-ball-sized fecalith in the terminal ileum with localized ulceration and thickening of the intestine.

Case 2.—A woman, aged 67, presented another unusual problem. Hemorrhoidectomy had been performed,. and the patient had constant pain for three months after the operation. Due to language difficulties, the complaints were ill-defined. Frequent digital examinations failed to reveal anything wrong. The symptoms were considered to be due to nervous tension. Eventually, proctoscopic examination disclosed a fecal impaction containing a gauze square as a nidus, the removal of which resulted in dramatic relief.

Comment

Typical case histories relative to the unusual problems presented by fecal impactions beyond the reach of the examining finger have been presented. It is not necessary to cite cases of the usual impactions occurring low in the rectum. We must think of the possibility, insert the finger in the rectum, make the diagnosis, and institute proper therapy.

Fecal impaction occurs when firm stool in the intestine or rectum can only be removed with the aid of the finger, enemas, or an operation. No age group is exempt, and any portion of the intestine may be involved, although the rectum is the most frequent site.

Fecal impaction may be caused by organic diseases, such as obstructing cancers, fissures, anal strictures, megacolon, paresis, or infantile paralysis. Diagnosis may be made by evaluation of the symptoms of obstruction, tenesmus, bleeding, and "false diarrhea," supplemented by careful physical examination, including digital examination of the rectum and proctosigmoidoscopic examination. A roentgenogram of the abdomen and barium enema are important.

Treatment, in functional cases, consists chiefly of cleansing the rectum and lower part of the intestine by digital manipulation and enemas. In the presence of organic strictures of the anorectal area, anesthesia may be required for proper examination and treatment. In the presence of benign or organic strictures of the intestine, it may be possible to insert a rectal tube with the aid of a sigmoidoscope proximal to the narrow segment and thus decompress the intestine without resorting to emergency colostomy.

Diagnosis and treatment of this common disorder frequently requires some uncommon judgment and exercise on the part of the clinician, but such effort should result in many grateful patients and prevent unnecessary operations. Because of the paucity of information on fecal impaction in the textbooks, we consider this subject to be timely and pertinent.

1447 Hamilton St. (Dr. Kratzer).

WAYS AND MEANS TO REDUCE INFANT MORTALITY DUE TO SUFFOCATION

IMPORTANCE OF CHOANAL ATRESIA

Henry H. Beinfield, M.D., Brooklyn, N. Y.

Most newborn infants breathe through the nose and open the mouth only to cry or feed. The inhibition against mouth-breathing is sometimes so strong that obstructing the nose leads to suffocation. This is believed to account for some asphyxial deaths in newborn infants, since bilateral choanal atresia may exist. Even unilateral choanal atresia can be fatal if the remaining normal passage is temporarily obstructed. The diagnosis is made by measuring the depth to which a metal probe can be passed into the nose. A depth of less than 32 mm. (1¼ in.) means atresia; a depth of more than 44 mm. (1¾ in.) means patency. Data on the causes of neonatal asphyxial death will not be reliable until pediatricians include the choanal patency test in their regular procedure for the physical examination of infants, but it is believed that a perceptible reduction of the mortality from neonatal asphyxia can be achieved by keeping in mind the possibility of choanal atresia.

Surveys and investigations have been made by committees in an attempt to find out how the number of needless neonatal deaths can be reduced. Although the presence of congenital choanal atresia (atresia of the posterior nares) has never been considered in these reports, this factor should be included, for a proper evaluation, as one of the causes of infant suffocation. Choanal atresia, bilateral and unilateral, is seldom recognized as one of the causes of asphyxia in newborn babies and in infants up to 5 months of age who are found dead in their cribs or carriages, but more attention should be given to this condition if infant mortality is to be reduced.[1] As a significant finding in suffocation, it is also a serious public health problem.

Choanal atresia was definitely seen and described as early as 1830 by Otto[2] as a cause of infant suffocation, and there can be no question that it is still an important factor. Several writers[3] have reported during the last few years that a number of infants were saved from suffocation when this diagnosis was made and the condition immediately dealt with. Since such reports usually appear in a specialty journal, most physicians are not as familiar with this condition as they should be. The purpose of this paper is to stimulate a wider interest in the importance of choanal atresia in infant suffocation.

McKibben[3e] has described the history, incidence, embryologic development of the normal choana, theories of the causation of atresia, anatomy, associated anomalies, symptoms, diagnosis, and treatment along with an extensive bibliography. Medical students should be taught about this anomaly, but most courses in anatomy and pediatrics at present do not mention the existence of choanal atresia.

Mechanics of Suffocation

When both nostrils are completely obstructed because of bilateral atresia, the infant is unable to get any air into his lungs and dies of suffocation with, possibly, only a diagnosis of atelectasis being given. Clinically, this symptom complex, which is

---

From the Department of Otolaryngology, Prospect Heights and Long Island College hospitals.

responsible for suffocation at birth, can be proved by pinching both nostrils of the newborn infant and watching the reaction. Signs of impending asphyxia will develop if the infant does not cry.

Unilateral atresia, which may occur up to 5 months of age, may be responsible when the infant is found dead in his crib or carriage. Although the contribution of this type of atresia to such deaths has not yet been substantiated by clinical study, I believe it is an important cause. The question is often asked, "Doesn't the infant open his mouth to get air to breathe, if he cannot breathe through his nose?" The answer is definitely "no." Thomson and Negus,[4] in 1937, stated that it is natural for an infant to breathe only through his nose. In other words, an infant will not normally open his mouth to breathe if he cannot breathe through his nose; as a matter of fact, he will close his mouth tighter in the effort of forced nasal breathing, cutting off the only other source of air, and will, therefore, suffocate. Thus, the normal and natural reflex, for adult or infant, is to breathe only through the nose, and mouth breathing is never normal at any age. Opening the mouth to breathe is purely a voluntary action, and infants up to 5 months of age do not usually have voluntary actions or movements. There are infants, however, who for some unknown reason breathe through the mouth at birth. Such an infant is an exception, however, and will not suffocate if he has bilateral choanal atresia. The anesthetist, pediatrician, and obstetrician as well as the general practitioner are, strangely enough, often unfamiliar with this reflex.

The mechanics of suffocation in an infant up to 5 months of age are as follows: First, an infant with bilateral complete nasal obstruction may suffocate at birth. Second, an infant with unilateral atresia or obstruction may suffocate at any time up to 5 months of age if conversion to bilateral obstruction occurs: When the mother places the baby on his abdomen, usually after he has been fed, with the side of the head or face so resting on the pillow or mattress as to close the airway of the clear or open nostril, complete bilateral obstruction may occur and the infant may suffocate.

Incidence

Infant mortality due to suffocation could be reduced if physicians were more aware of the possibility of choanal atresia. This congenital anomaly should be considered in all cases of asphyxia neonatorum; when it is recognized, proper measures should be immediately instituted to correct it.[4A] It is much more prevalent than one can imagine. The medical examiner and pathologist are frequently at a loss to explain the cause of death at autopsy in these cases because the nose is seldom examined or considered responsible for suffocation, with the result that the final report may state "cause unknown."[5]

No vital statistics agency in the United States lists atresia as a cause of death by suffocation. All such cases of suffocation are usually tabulated with atelectasis under the International List code number 762. I am informed that, to supply statistics on atresia, the report should specifically state "atresia" as cause of the suffocation or atelectasis.[6] The diagnosis of atresia can then be listed separately under the International List code number 759—congenital malformations of respiratory system—where it belongs. Autopsy is not done in many infants who die of suffocation, and, for the sake of completing the death certificate, pneumonia is often given as a cause.[7] This practice creates wrong statistics for pneumonia. Pathologists frequently report finding fulminating pneumonia as the only cause of death. In many cases, this could well be due to terminal changes and not to true pneumonia. Statistics furnished by the Health Department of the City of New York for 1951 showed that there were 162,755 live births, that 729 deaths were classified under International List code number 762 —postnatal asphyxia and atelectasis—and that, of these deaths, 389 (53%) were of infants under one day of age. No one knows how many deaths might have been due to choanal atresia, because the posterior nares were not examined at autopsy.

Anatomy, Diagnosis, and Treatment

Atresia of the nares at the junction of the hard and soft palate completely obstructs the passage of air through the nose. It may occur on one or both sides. The obstruction is usually of a completely bony nature, although it may be partly bony or only membranous. In the completely bony obstruction the nasal mucous membrane covers it in front and the pharyngeal mucous membrane covers it posteriorly. Embryologically, atresia is due to a failure of the buccopharyngeal membrane to open. Stupka[8] describes many types of atresia of the posterior nares. Other facial anomalies may be associated with this condition.[9]

Diagnosis.—In all cases of impending asphyxia, the anesthetist or the physician in charge of the newborn infant should immediately rule out bilateral choanal atresia. The difficulty in creating a clear airway may be found only in the nose. It is simple to make a diagnosis of choanal atresia. In the newborn infant, a metal probe should be passed into the nose until an obstruction is met. With the point on the probe carefully held where it meets the rim of the nostril, the probe is then removed. The distance is measured from the tip of the probe to the point held by the finger. If this distance measures 1¼ in. or less a diagnosis of choanal atresia can be made. If it measures 1¾ in., atresia is not present. If a no. 12 catheter cannot be passed into the pharynx, atresia can be suspected and confirmed by x-ray examination with the use of iodized oil (Lipiodol).

When unilateral atresia is suspected in infants up to 5 months of age, one may also try closing each nostril separately to determine which side of the nose is involved. If, after one nostril is closed, signs of suffocation appear, atresia of the opposite side of the nose should be suspected and checked. This test is of no value if the infant cries. When neither atelectasis nor other cause of death is apparent at autopsy, the pathologist or medical examiner should investigate the nose to determine if a congenital obstruction is present.

The only sign of bilateral atresia of the posterior nares is impending suffocation immediately after birth. One should watch for certain symptoms that could indicate unilateral choanal atresia to prevent unexpected and sudden death in infants up to 5 months of age. A thick, glairy mucus may be noted *persistently discharging from one nostril, or the* infant may have difficulty in breathing while nursing. The posterior nares should be examined in all such cases.

Treatment.—In a newborn infant with bilateral atresia in whom asphyxia is imminent, the mouth should be opened immediately and kept open with an anesthetist's infant-size airway.[4A] In this way the danger of anoxia can be overcome. The airway should be secured with adhesive tape strips placed across it and over the cheeks. This emergency procedure will save the life of the infant, and a nasal airway can later be established surgically. It is recommended that a clear nasal airway be obtained surgically within 24 to 48 hours after birth.[10] The airway in the mouth permits inhalation of enough air to barely sustain life; obviously, much more air is received through the nose when both nares are clear. Feeding is done by stomach tube or bottle. Sucking mucus out of the nose with a catheter or use of a resuscitator will not clear the nose if a complete obstruction is present.

When unilateral atresia is recognized, the mother should be warned against placing the infant down so as to close off the clear side of the nose. Operation for correction of unilateral atresia is not recommended during infancy. It is best to wait until the child is about 12 years of age or older, when a more satisfactory surgical procedure can be performed.[9]

Comment

It has been definitely established that bilateral choanal atresia is one of the causes responsible for suffocation of the newborn infant. The anesthetist or physician who is in charge of the infant immediately after delivery should first investigate the posterior nares in every case of impending asphyxia.

It has not yet been determined whether unilateral atresia is present or responsible for the sudden deaths of infants, but, in my belief, this could be an important factor. If a bilateral obstruction will cause suffocation, a unilateral obstruction due to atresia will produce the same result when, under favorable conditions, it is converted into a bilateral obstruction. This still remains a problem for further investigation and confirmation.

Pathologists and medical examiners seldom examine the nose for atresia in such cases to find the cause of death and often report "cause unknown." They could be of great help here by simply investigating the nares with a metal probe or catheter as one of the procedures in the autopsy examination.

I do not consider hydrocephalus, occasionally reported as a finding in these cases, as a congenital anomaly but rather as a complication, due to the spinal canal having been penetrated in the region between the atlas and the axis vertebrae as a result of improper surgery.[10]

A suggested plan to reduce infant mortality due to suffocation resulting from choanal atresia is as follows: 1. Federal, state, and local boards of health should inform every physician of the danger of choanal atresia. 2. Medical schools should teach the importance of this condition in courses on anatomy and pediatrics. 3. Committees investigating the reduction of neonatal deaths should include choanal atresia in their studies. 4. In every case of asphyxia neonatorum a notation should be made on the infant's chart that an examination for atresia of the posterior nares was made. 5. Every medical examiner and pathologist should examine the posterior nares in every newborn baby and infant up to 5 months of age when atelectasis is present or no other cause of death can be found. 6. When the cause of death by suffocation has been proved to be choanal atresia, it should be reported as such so that a proper tabulation of its incidence, which does not exist at present, can be made.

DURATION OF SEROIMMUNITY AFTER INJECTION WITH ULTRAVIOLET-IRRADIATED POLIOMYELITIS VACCINE

ROLE OF BOOSTER INOCULATIONS

Albert M. Wolf, M.D., Howard J. Shaughnessy, Ph.D., Martha Janota, M.S., James W. Chapman, M.D.
Ruth E. Church, M.D.
and
Mildred Moore, B.A., Chicago

The degree and duration of immunity induced by injections of killed poliomyelitis vaccine were studied in 4,000 children. A smaller serologically negative group received special study. Antibody titers were measured before and after the primary immunization, before and after the first booster injection, and before and after the second booster injection. The average immune status was raised by the primary vaccination, but it declined during the ensuing year, was raised to a higher level by the first booster, declined less thereafter, and reached its highest level after the second booster. The response to type 2 antigen was better than the responses to types 1 and 3. There were indications that the commercial vaccine used in the later phases of the study was more potent than the experimental vaccine used in the beginning. The authors recommend that the primary series of three injections of ultraviolet-irradiated formalin-treated poliomyelitis vaccine be followed by at least one and possibly two booster injections at yearly intervals.

Additional information is needed concerning the duration of immunity from vaccination with killed virus poliomyelitis vaccine. Probably some years must elapse before a final answer can be obtained, but in the meantime it appears that studies of the persistence of poliomyelitis antibodies after primary immunization and booster inoculations may be an index of the durability of immunity. It is realized that possession of antibodies against poliomyelitis and real immunity against the paralytic disease may be two different phenomena, but it is generally assumed that the two are significantly correlated. There have been numerous studies on antibody response after vaccination, but only a few studies have been reported on the duration of seroimmunity after vaccination; among them are those by Salk,[1] Armstrong and associates,[2] and Brown and co-workers.[3]

In previous reports,[4] our group showed that (*a*) a combination of ultraviolet irradiation and mild heat consistently inactivated all three types of poliomyelitis virus derived from monkey tissue culture and (*b*) the resultant poliomyelitis vaccine was safe and evoked significant antibody formation in children. These experimental vaccines were used to inoculate some 4,000 children in Morgan County, Ill., in an investigation made in cooperation with the Illinois Department of Public Health and the Morgan County Health Department. One of the principal reasons for the selection of this area was the low incidence of poliomyelitis over a period of years previous to the study. These children have been observed for two to five years after immuni-

zation; none has developed poliomyelitis. The group is small, and there has been very little poliomyelitis in Morgan County or nearby during the period of observation; hence, no definite deductions can be made concerning clinical immunity.

More definite deductions regarding duration of immunity may be based on serial studies of poliomyelitis antibodies in the serums of immunized children. Our limited facilities precluded testing of all of the immunized children for antibody responses. By preliminary screening we selected children who were largely lacking in antibodies and concentrated on this picked group for further study. It is possible that some of these children may have had antibodies not demonstrable at the time of inclusion in the study. Obviously, this reservation applies to all studies by all methods and perhaps explains the effectiveness on occasion of a single injection. There was a progressive decrease in the size of the study group over the period of the study, so that results were not always obtainable on exactly the children from whom they were desired. These later groups were from the original intensive study group, and the only selection was based on the willingness of the parents to have blood samples taken and reinjection done.

Methods

All injections were with our experimental vaccine except as will be noted. Screen assays of antibodies were performed by the roller tube method throughout. It is recognized that this method gives titers less than those shown by metabolic inhibition, probably in a ratio of approximately one to four.[4a] Sabin[5] has indicated that antibodies demonstrated by the cytopathogenic test in roller tubes have higher avidity than those demonstrated by metabolic inhibition. He has also shown that antibodies of the high avidity type are developed as a result of natural infection and are, therefore, presumably a good index of real immunity.

Children in the group analyzed here were tested for antibodies (*a*) before primary immunization of three injections at 1-to-14-day intervals; (*b*) after primary immunization at 7 to 30 days after the third injection; (*c*) immediately before our first booster 12 to 36 months after primary injection; (*d*) about 7 to 21 days after first booster injection; (*e*) immediately before the second booster at 12 to 24 months after the first booster; and (*f*) about 7 to 21 days after the second booster.

Results

Specific titers are shown in table 1 and summarized in table 2. Certain findings are outstanding. The response to the type 2 component of the vaccine is relatively greater than to the type 1 and type 3 components. Of 83 children lacking antitype 2 antibodies initially, all showed such antibodies after the primary injection and 82 showed such antibodies in all tests thereafter, while one produced antibodies after the primary injection but seemed to lack them before the first booster injection; this child responded well to the booster injection and showed antitype 2 antibodies in all subsequent tests. Thus, immunity generated by the type 2 component

Table 2.—*Antibodies Against Poliomyelitis*

		Negative Against Type						Mean Titer, Type		
		1		2		3				
	No. of Children	No.	%	No.	%	No.	%	1	2	3
Preprimary injections.	105	96	92	83	80	88	84	6	7	10
Postprimary injections	105	12	12	0	0	18	17	48	82	72
Prebooster 1 (12-36 mo. later).....	96	33	34	1	1	27	28	12	73	42
Postbooster 1	80	1	1	0	0	5	6	182	328	147
Prebooster 2 (12-24 mo. later)	56	5	9	0	0	8	14	13	50	17
Postbooster 2	14	0	0	0	0	1	7	487	364	243

of the experimental vaccines used may be considered in excess of 98%. In contrast, the responses to the type 1 and type 3 components of the experimental vaccines were less but still quite good. The incidence of those lacking antitype 1 antibodies (negatives) was 92% preimmunization but fell to 12% after the primary injection, had risen to 34% at the prebooster testing some 12 to 36 months later, dropped to 1% after the first booster injection, and had again risen but only to 9% at testing before the second booster injection 12 to 24 months later. All children tested after the second booster injection showed antitype 1 antibodies. Data for the type 3 component are similar to those for type 1. Thus, with our experimental vaccines the immunity generated against type 1 and type 3 poliomyelitis virus seemed to be weaker with lower titers and a tendency was seen for the antibody levels to fall below the threshold of our test method and return to zero level.

From general immunological considerations it seems likely that poliomyelitis antibodies once produced are present for life, although, perhaps, at very low levels, and that the host will display a rapid anamnestic reaction to either booster injection or actual virus exposure. Thus, the host who has once shown antibodies is probably clinically immune. Nevertheless, a persistence of demonstrable antibodies like those demonstrated against type 2 is to be preferred.

The value of a first booster injection is clear, and the immune status after the first booster is better than after the primary injection in the following comparisons: (*a*) the percentage of negative responses is less; (*b*) the average titer is higher; and (*c*) the persistence of demonstrable antibodies is better.

The improvement created by the first booster leaves a fairly satisfactory status of 86 to 100% serologic immunity; additional booster injections seem less important, although obviously they would tend to improve the average immune status.

In the latter part of this study, as our own experimental vaccines ceased to be available, use was made of a commercial poliomyelitis vaccine prepared by a combination of ultraviolet irradiation and dilute formalin. The use of this vaccine for the first booster injection in 26 children among those tested after the first booster permits comparison with the remaining 54 who received booster injections of our experimental material. The comparison is altogether favorable to the later-produced commercial product. All children receiving booster injections with this material showed demonstrable antibodies against all three types when tested after the booster injection and the average titers were higher in a ratio of eight to one (type 1), two to one (type 2), and two to one (type 3).

Comment

The durability of seroimmunity to poliomyelitis after vaccination with ultraviolet-irradiated vaccines has been studied for two to five years during which time some children received one and others two postbooster inoculations. In most instances the children had received their three initial injections of vaccine so close together that it is probable that what we are calling the first postbooster dose might in other time schedules be called the final dose of the primary series. Seroimmunity followed exactly the pattern that might have been expected. There was a good response after the primary series which fell off somewhat during the next 12 to 36 months; after a first booster injection the antibody levels reached a higher level and fell less than after the primary immunization; after a second booster there was an even better response to even higher titers. As in previous studies by others and by ourselves, the responses to types 1 and 3 antigens were not as good as to type 2. Possibly the latter is a better antigen or the response to it is conditioned by prior experience to a greater extent than is true of the other two antigens. The evidence from this study suggests the desirability of at least one and possibly two booster injections at yearly intervals.

FAMILIAL PERIODIC DISEASE WITH RENAL DAMAGE

Israel Alkalay, M.D., Maxim Shenfield, M.D.
and
Emmanuel Levy, M.D., Ph.D., Affula, Israel

A 16-year-old boy was hospitalized with symptoms and signs of acute glomerulonephritis. He had suffered since childhood from recurring attacks of fever with abdominal pain and rigidity. Treatment with various antibiotics was unavailing. Anemia increased and renal failure progressed until death, and autopsy disclosed an appendectomy scar, general amyloidosis of the secondary type, terminal pericarditis, and bronchopneumonia. The father and one brother of the patient had each undergone appendectomy for similar recurrent episodes of abdominal pain, and another brother had a similar history but without appendectomy. A fourth brother was healthy, as was the mother. It is believed that the four cases described were instances of familial periodic disease or recurrent polyserositis and that this possibility should be kept in mind in patients with symptoms of either nephritis or appendicitis.

The disease described by Reimann[1] and termed by him "periodic disease" has been increasingly recognized and reported in Israel, although different names are sometimes applied. Heller and associates called it familial Mediterranean fever,[2] and Rachmilewitz and associates termed it recurrent polyserositis.[3] These studies, along with those of Reimann[4] and Mamou,[5] may be regarded as having established the independent existence of this disease beyond question. It is interesting that all the patients have their origin in Mediterranean countries and the majority are Jews, Armenians, and Arabs, with a few patients among Turks and Italians. A few reports have described patients in whom renal damage was present (Mamou and Cattan,[6] Heller and co-workers,[2] and Shapira[7]). Mamou and Cattan[6] in particular stressed the importance of renal involvement in periodic disease and described a family in which six members suffered from periodic disease, three of whom died from uremia.

The present communication concerns a Jewish family from Spanish Morocco, four members of which were known to suffer from periodic disease, and all of whom showed signs of renal damage, one having died in the terminal stages of renal failure; the postmortem findings of the latter are included in this report. The family in question consisted of a father and four sons, all except the youngest son having been admitted to hospital for the purpose of this study.

Report of Cases

CASE 1.—In January, 1957, a 16-year-old boy from Spanish Morocco was admitted with a tentative diagnosis of acute glomerulonephritis. Two weeks prior to admission he had suffered from an attack of tonsillitis which had been followed a few days later by swelling of the ankles and eyelids. He gave a history of suffering since childhood from recurring irregular attacks of abdominal pain lasting one day, during which the abdomen became "as hard as a stone"; between attacks he felt well. At the age of 10 years appendectomy was performed, but the attacks continued as previously. Examination revealed edema of the eyelids and ankles. The blood pressure was 140-150/100 mm. Hg. A systolic murmur was heard over the apex. The spleen was palpable to 6 cm. below the costal margin. The liver was not palpable. The laboratory findings were as follows: hemoglobin level, 10 Gm. per 100 ml.; red blood cell count, 3,650,000 per cubic millimeter; white blood cell count, 15,000 per cubic millimeter; total protein level, 4.5 Gm. per 100 ml.; albumin level, 1.7 Gm. per 100 ml.; globulin level, 2.8 Gm. per 100 ml.; blood cholesterol level, 230 mg. per 100 ml.; urea level, 100 mg. per 100 ml. The Congo red test showed 33% retention in blood; blood sedimentation rate (Westergren method) was 140 mm. the first hour and 150 mm. the second hour; the results of the blood potassium, sodium, chloride, carbon dioxide–combining power, and uric acid tests were within normal limits. Examination of the urine showed albuminuria with moderate numbers of white blood cells, red blood cells, and casts.

During the first few weeks of his stay in hospital, a low-grade pyrexia continued despite the administration of various antibiotics. Blood culture and serologic reactions were negative. The antistreptolysin titer was 128 units. The temperature slowly returned to normal, there being attacks of fever and abdominal pain lasting for only one day on the 64th, 72nd, and 81st days of hospitalization. Diastase and porphyrobilinogen were not found in the urine. The patient was admitted again in June, 1957, when the main finding was more severe anemia (red blood cell count, 2,760,000 per cubic millimeter). At the last admission, January, 1958, there was increasing anemia and progressive renal

---

From the Department of Internal Medicine and the Institute of Pathology, Central Emek Hospital, Kupat Holim.

failure (blood urea level, 369 mg. per 100 ml. and uric acid level, 11.6 mg. per 100 ml.) until death.

Postmortem Findings.—At autopsy well-marked emaciation and pallor were present. On the front of the trunk and extensor surfaces of the limbs a skin eruption was to be seen. There was an old operation scar in the right iliac fossa. Both pleural cavities showed marked adhesions, particularly at the lung bases; there was no fluid. The larynx and trachea were normal. The bronchi contained frothy mucus. The lungs weighed 1,300 Gm. and showed generalized edema with bronchopneumonic changes in both bases, with some petechial hemorrhages on the outer surfaces. The pericardial sac contained an excess of straw-colored fluid. The outer surface of the heart showed fresh pericarditis. The heart weighed 300 Gm. and showed no other special features. The spleen weighed 340 Gm. and was enlarged and firm. Apart from a few petechial hemorrhages in the mucosa of the stomach, no special features were noted in the gastrointestinal tract; the appendix was absent. The liver weighed 2,120 Gm. and was enlarged and pale.

The kidneys appeared small, the combined weight being 150 Gm. The capsules stripped fairly easily, with few adhesions. The cut surfaces showed marked pallor with some blurring of the corticomedullary markings. The remainder of the genitourinary system showed no special features. The brain weighed 1,480 Gm. and showed edema but no other special features macroscopically. The pituitary, thyroid, and adrenal glands appeared normal. Marked diffuse amyloidosis was found in the kidneys, spleen, and adrenal glands, but not in the liver; the amyloid material gave the typical staining reactions of so-called secondary amyloidosis. The skin showed the changes of nonspecific dermatitis. The remaining tissues and organs showed no special features. The findings were summarized as showing generalized amyloidosis of secondary type with terminal pericarditis and bronchopneumonia.

Case 2.—The father, aged 47 years, also gave a history of attacks of severe abdominal pain from childhood, the pain lasting from 24 to 48 hours and accompanied by temperatures up to 101 F (38.3 C). Between attacks of pain he felt well and did hard physical work. At the age of 12 years appendectomy was performed, with no influence on subsequent attacks. At the age of 20 years he suffered from gonorrhea, and at this time examination revealed albuminuria. He could remember only one year when he was completely free from pain. At the time of admission, the attacks of abdominal pain had been occurring every 13 to 20 days, accompanied by pyrexia up to 102 F (39 C). The condition of eight siblings was unknown; however, he stated that his father, who died at the age of 63 years, also had suffered from attacks of abdominal pain every one or two weeks, the pain lasting one to two days.

Physical examination revealed no special findings. Examination of the urine showed specific gravity to be 1.008, 1 to 2 leukocytes and erythrocytes per high-power field, and occasional hyaline and granular casts. Urea clearance was 66% of normal. Examination of the fundus oculi was reported as follows by Dr. Sachs: "Dark red macula around which are white areas of retinal ischemia due to obstruction of the choroidal capillaries, and in addition marked Gun signs." During his stay in hospital, one attack of abdominal pain was witnessed, accompanied by pyrexia up to 102 F and leukocytosis (with an increase in leukocytes from 6,450 to 9,600 per cubic millimeter).

During the attack, examination of urine for porphyrobilinogen was negative. All signs of the attack disappeared after 24 hours. X-rays of the chest, stomach, gallbladder, and urinary tract showed no abnormal findings. Blood chemical examinations were negative (levels of urea, uric acid, creatinin, cholesterol, and proteins were all within normal limits). The findings were summarized as showing periodic disease with slight renal damage.

Case 3.—The 12-year-old son, from the age of 9 years, had suffered from attacks of severe abdominal pain every 8 to 20 days, accompanied sometimes by pain in the extremities and with pyrexia up to 102 F. He was admitted to hospital in Morocco at the age of 9 years because of suspected nephritis. Appendectomy was performed at the age of 10 years, but the mother related that the surgeon had informed her that the appendix was not inflamed. The attacks of pain reappeared six months after the operation and recurred to the time of admission, each attack lasting up to 24 hours; between attacks he felt well.

There were no abnormal findings on physical examination. Blood pressure was 110/70 mm. Hg. During an attack the blood sedimentation rate (Westergren method) was 34 mm. the first hour and 75 mm. the second hour. The only abnormal findings were in the urine, examination of which showed a specific gravity of 1.016, traces of albumin, and occasional erythrocytes and leukocytes in each microscopic field. Liver function tests were normal. X-rays of the chest, gallbladder, and urinary tract were normal. Examination of the fundus oculi showed a normal appearance. A typical attack of abdominal pain was witnessed, accompanied by pyrexia up to 101 F and leukocytosis, with 16,000 leukocytes per cubic millimeter. All the signs disappeared the next day. During the attack, examination of the urine was negative for porphyrobilinogen. The findings were summarized as being those of periodic disease with slight albuminuria.

Case 4.—Another son also suffered from the age of 5 years from attacks of abdominal pain every 8 to 10 days, accompanied by pyrexia up to 102 F;

the attacks usually subsided in 6 to 12 hours with administration of analgesics. From the age of 9 years the abdominal attacks ceased, but since then he has had attacks of pain in the chest, mainly on the right side. Six months before his admission he had an attack of angina followed two weeks later by edema of the eyelids and ankles. The results of urine examination are not available. Clinical examination was normal. Blood pressure was 130/80 mm. Hg. The urine showed traces of albumin, with leukocytes and occasional red blood cells in each microscopic field. Other laboratory findings were normal. X-rays of the chest, stomach, gallbladder, and urinary tract were normal. The fundi oculi were normal. The findings were summarized as showing periodic disease characterized by abdominal pain in early childhood which has been replaced by stethalgia; slight urinary abnormalities were also present.

The fourth son, 7 years of age, has been healthy apart from the usual childhood illnesses, and there is no present evidence of periodic disease. The mother of the family is healthy, and there is no blood relationship between her and her husband, the father of the family.

Comment

Four members of one family suffered from periodic disease and showed evidence of renal damage; one of these died in renal failure and postmortem examination revealed the presence of amyloidosis. In this patient there was an episode of acute glomerulonephritis about a year before death. Although some authors describe the possibility of various forms of nephritis, including acute nephritis, occurring in periodic disease (Mamou [5] and Benhamou and associates [8]), it is probable that in the patient described the attack of acute nephritis was superimposed on the basic condition.

The family history suggests the possibility of hereditary transmission as a dominant factor; this is in agreement with the view put forward by Heller and associates.[2b]

It is considered that the renal damage is an important and frequent sign of periodic disease, as stressed by Mamou and Cattan [6] and confirmed by Heller and associates,[2b] and this complication affects the prognosis which was formerly considered to be benign. It is not clear whether the renal damage is an integral part of the disease or should be regarded as a complication to which these patients are more prone. In any case it is important that the possibility of periodic disease should be considered in every case of obscure nephritis.

CHRONIC HYPOVENTILATION IN THE OBESE PATIENT.—The symptoms and signs due to the hypoventilation syndrome in the obese individual develop insidiously, and frequently have been present for a long time without patient or relatives realizing their presence. The obese patient who is hypoventilating might therefore be likened to the myxoedematous individual. In both, the insidious nature of the development of the signs and symptoms and the resulting dulling of the sensorium, and possibly confusion, frequently delay the initial visit to the physician for medical attention. The insidiousness of this syndrome is pointed out by the fact that it was only in retrospect that the family volunteered a history of headache and progressive fatigue.

Thus it can be seen that even in the absence of obvious clinical lung or heart disease, the obese individual may be suffering from deleterious effects on the respiratory and haematological systems, which in turn may affect the sensorium and produce neurological signs. These far-reaching effects of obesity emphasize and underline the preventive and therapeutic implications of excessive weight, with or without pulmonary disease.—Reuben M. Cherniack, M.D., Respiratory Effects of Obesity, *The Canadian Medical Association Journal*, April 15, 1959.

MANAGEMENT OF ARTERIOSCLEROSIS OBLITERANS OF THE EXTREMITIES

Fay A. LeFevre, M.D., Cahid Corbacioglu, M.D., Alfred W. Humphries, M.D.
and
Victor G. deWolfe, M.D., Cleveland

The most common vascular disease that involves the extremities is arteriosclerosis obliterans. It occurs most frequently during the fourth, fifth, or sixth decade of life and may disable its victim at the peak of his career, thus making treatment a matter of utmost importance.

Although angiography has been a well-established technical procedure for several years,[1] its clinical application in diagnosis and prognosis has become important only fairly recently, concomitant with the development of successful techniques for arterial grafting. These two procedures, angiography and arterial grafting, have altered the treatment of peripheral arterial disease to the extent that currently a decision must be made in each case as to whether or not the patient is a suitable candidate for arterial grafting. To assist the clinician in making this decision, knowledge of the natural course of the disease is most valuable. In this report we shall discuss the diagnosis and natural course of arteriosclerosis obliterans, outline the diagnostic criteria for selecting patients for angiography and for arterial grafting, and summarize our results of this type of surgical treatment for arteriosclerosis obliterans.

A follow-up study of 500 patients with arteriosclerosis obliterans indicates that approximately 75% show little progression of the disease over a five-year period. Angiography is the only method that demonstrates the segmental type of occlusion. All patients with severe ischemia, with or without gangrene, should have the benefit of angiographic study to determine the feasibility of arterial grafting, which may be the preferred treatment. Morbidity in patients undergoing arteriography has been 0.1%, with no deaths. The effect of sympathectomy on the progress of arteriosclerosis obliterans is difficult to determine.

Diagnosis of Arteriosclerosis Obliterans

The diagnosis of arteriosclerosis obliterans can be readily established by evaluation of the history and physical findings on examination. As a rule, special studies such as temperature and oscillometric recordings are not essential. The most common symptom is intermittent claudication, usually described as a cramp-like pain related to walking or to exercise (fig. 1). Claudication may occur at any level in the lower extremities, depending on the site of the arterial obstruction (fig. 2). Arteriosclerosis obliterans is a common though frequently overlooked cause of low back pain related to obstruction of the abdominal aorta or of the common iliac arteries. If claudication is present the chief physical finding will be reduced or absent peripheral pulsations. Pulse changes can be readily detected by palpation at the usual levels and are related to the level and extent of obstruction. In addition, patients may or may not experience coldness of the extremities and show evidence of trophic changes. These features are related to the rate of progress of the disease and to the extent of development of collateral circulation.

A positive diagnosis of arteriosclerosis obliterans, therefore, can be made in most cases from a typical history of intermittent claudication along with the clinical finding of abnormally low or absent peripheral pulses.

Although thromboangiitis obliterans and problems of acute arterial occlusion resulting from embolism may give rise to similar findings, they are seen infrequently, and the features of differential diagnosis have been well documented.[2]

Natural History and Progression of Arteriosclerosis Obliterans

The evaluation of any medical problem is aided considerably by an understanding of the prognosis or possible progression of the disease. This is especially true of arteriosclerosis obliterans.

In 1940 Hines and Barker[3] reported a study of 280 cases of arteriosclerosis obliterans. Of 116 patients adequately followed up 54.6% died within the first three years. Of the 280 patients 70 underwent amputation. Massarelli and Estes,[4] in an eight-year follow-up study of patients who had arteriosclerosis of the abdominal aorta and the iliac arteries, disclosed survival rates of 47% at the end of the fifth year and 18% at the end of the eighth year. They also reported that of the 57 patients

Read before the Section on Internal Medicine at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

followed up for two years 79% had no progression of the disease. Silbert and Zazeela[5] observed the course in 1,198 patients with arteriosclerosis obliterans and reported in detail the prognosis in those patients. Beckwith and co-workers[6] made a six-year follow-up study of 65 patients with aortoiliac thrombosis, 22 of whom died while under observation; death usually was related to disease of the renal, coronary, or cerebral arteries.

Our study is based on the records of 500 consecutive patients with arteriosclerosis obliterans seen at the Cleveland Clinic from 1950 through 1952, providing a minimal follow-up evaluation period of five years. The average age of the patients when first examined was 60 years; 20.2% were women and 79.8% were men. All of the cases satisfied the clinical criteria for diagnosis as outlined above. The sites of the disease were the abdominal aorta and the peripheral arteries of the lower extremities. Patients with aneurysm were not included in this series. The period in which these patients were seen predated the advent of arterial grafting at the Cleveland Clinic; 86 of the patients underwent sympathectomy. All of the patients were instructed in the general care of the limbs and were advised to refrain from the use of tobacco. Diabetic patients were given special instructions.

The five-year survival rate after the time of diagnosis is graphed in figure 3. As might be expected, the survival rate of the nondiabetic group (59.0%) is slightly higher than that of the diabetic group (52.7%), with the five-year survival rate of the total group being 57.3%. However, the presence of diabetes appeared to be of less importance in relation to five-year survival than the presence of arteriosclerosis involving other systems, chiefly cerebral and cardiac. This correlation is shown in figure 4. There was survival of 65.6% of patients who had no clinical evidence of arteriosclerosis elsewhere and 48.0% of patients who had evidence of arteriosclerosis elsewhere. The incidence of diabetes was essentially the same in these two groups. Of the total of 500 patients 212 (42.4%) had cardiac or cerebral involvement. Of these 67 were diabetic, or 47.5% of 141 diabetic patients in the series, and 145 were nondiabetic, 40.3% of 359 nondiabetic patients.

Fig. 2.—Relation of level of arterial obstruction to site of claudication.

In our total series, adequate follow-up by clinical evaluation was obtained in 185 cases. The degree of progress was determined and classified as shown in table 1.

The effect of sympathectomy on the progress of the disease and its relation to the incidence of amputation is difficult to determine. This is in part due to the fact that patients undergoing sympathectomies were in general the critically ill patients with advanced disease. In our series of 185 patients 37 (20%) underwent sympathectomy, of whom 12 (32.4%) improved, 10 (27.1%) remained the same, and 15 (40.5%) continued to become worse. The relationship of sympathectomy to diabetes is shown in table 2. Although there were fewer diabetic than nondiabetic patients in this series 60% of the diabetic patients became worse after sympathectomy, as compared to 33.3% of the nondiabetic patients.

The incidence of amputation in the total series of 185 patients was 11.9% (20.7% of the diabetic and 8.3% of the nondiabetic patients). Plasma cholesterol determinations were made for 130 patients. The average value was 236 mg. per 100 ml., the range being from 113 to 580 mg. per 100 ml. There appeared to be no correlation between the plasma cholesterol level and the degree or progress of the disease.

Table 1.—*Five-Year Follow-up Study of 185 Patients with Arteriosclerosis Obliterans*

Condition	Total Patients		Nondiabetic Patients		Diabetic Patients	
	No.	%	No.	%	No.	%
Improved	48	25.9	40	30.3	8	15
Unchanged	90	48.6	62	47.0	28	53
Worse	47	25.4	30	22.7	17	32
Total	185	100.0	132	100.0	53	100

Selection of Patients for Angiography

From the above analysis of the natural progression of arteriosclerosis obliterans it is clear that 75% of the patients studied either remained the same or improved during a five-year period. This would indicate that in about one patient in four the disease progresses to the extent that measures other than conservative ones are required in order to prevent or retard the necessity for amputation. If, in this group, the presence of segmental arteriosclerosis obliterans can be determined, it may be possible to reestablish circulation by arterial grafting. The following three groupings were used to select patients for angiography, the only means by which the presence of a segmental occlusion can be determined.

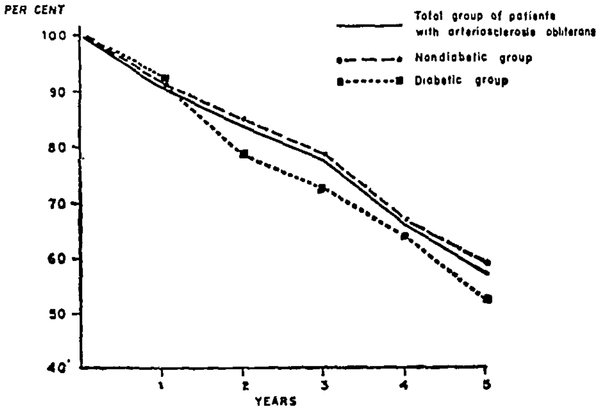

Fig. 3.—Five-year survival rate of 500 patients with arteriosclerosis obliterans, with comparison of diabetic and nondiabetic groups.

Group 1.—Patients Without Progressive Intermittent Claudication but Who Consider Themselves Disabled.—From time to time we see relatively young patients who have claudication after walking for one or two blocks. Even though the disease has been symptomatically stationary, they are unable to carry on their business duties and social activities because of their limitations in walking. Patients in this category may well deserve further investigation by angiography.

Group 2.—Patients With Progressive Intermittent Claudication With or Without Good Nutrition of the Limbs.—Regardless of the nutrition of the affected extremity progressive claudication indicates advancing disease. The necessity for angiography depends on the speed of the progression, and each case must be assessed individually. Some patients show rapid progression during the first few months after the onset of symptoms. They may then show no progression, however, because of formation of collateral circulation. In the patient with slow advancement it may be good judgment for the physician to observe the patient at monthly intervals, with the understanding that he must see the patient at once if there is a more rapid or radical change. In patients who have continued rapidly advancing disease, however, acute thrombotic occlusion may develop, and these patients should be considered candidates for early angiography. In such cases, if the occlusion is caused by segmental disease, acute ischemia of the limb may be prevented by early arterial grafting.

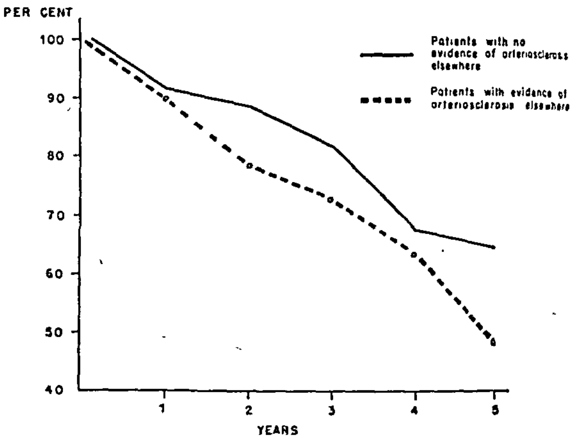

Fig. 4.—Five-year survival rate with comparison of patients having no evidence of arteriosclerosis elsewhere and those having evidence of other arteriosclerosis, chiefly cerebral or cardiac.

Table 2.—*Status of 37 of 185 Patients After Sympathectomy for Arteriosclerosis Obliterans*

Status After Sympathectomy	Nondiabetic Patients (27 of 132)		Diabetic Patients (10 of 53)	
	No.	%	No.	%
Improved	11	40.7	1	10
Unchanged	7	26.0	3	30
Worse	9	33.3	6	60

Group 3.—Patients With Rest Pain With or Without Gangrene.—The presence of rest pain indicates a severely ischemic limb and may be the forerunner of gangrene. Rest pain demands emergency treatment, and patients in this group should be hospitalized for angiographic studies in addition to

general vascular care. Even in the presence of gangrene angiograms must be made, as the limbs sometimes can be saved if arterial grafting is possible.

During the four-year period 1954-1957 more than 1,000 angiograms were made at the Cleveland Clinic, over half of which disclosed evidence of segmental arteriosclerosis obliterans (fig. 5). The morbidity in our patients undergoing angiography has been 0.1%, with no deaths.

Selection of Patients for Arterial Grafting

By adhering to the above criteria for the selection of patients for angiographic study we can determine the candidates for arterial grafting—provided a proper segmental type of occlusion is demonstrated. In patients in group 1 arterial grafting should be elective. The actual importance of the disability should be clearly determined, and in cases of this type the physician must advise the patient to the best of his judgment about the chance for recovery and improvement. In patients in group 2, especially if claudication is rapidly advancing, arterial grafting should be recommended. All patients in group 3 should undergo grafting, provided the angiograms indicate that it is technically possible. In all three groups the patient's general state of health must be considered before surgery is recommended. In patients in group 3, however, grafting may be considered an emergency procedure even in the poor-risk candidate.

For arterial grafting, as for all surgical procedures, it is not possible to outline rigid criteria as a strict guide for distinguishing operable from inoperable conditions. Each patient must be considered individually, but the grouping as outlined has proved helpful as a general guide in the selection of patients. Although angiograms are the best guide to the feasibility of surgery, we have encountered a few cases in which the angiograms indicated borderline operability, yet grafting was technically infeasible. We also have seen several cases in which the reverse was true: the angiograms indicated inoperability, yet grafting was possible. The above criteria for selection of cases for grafting do not apply to patients with aneurysm.

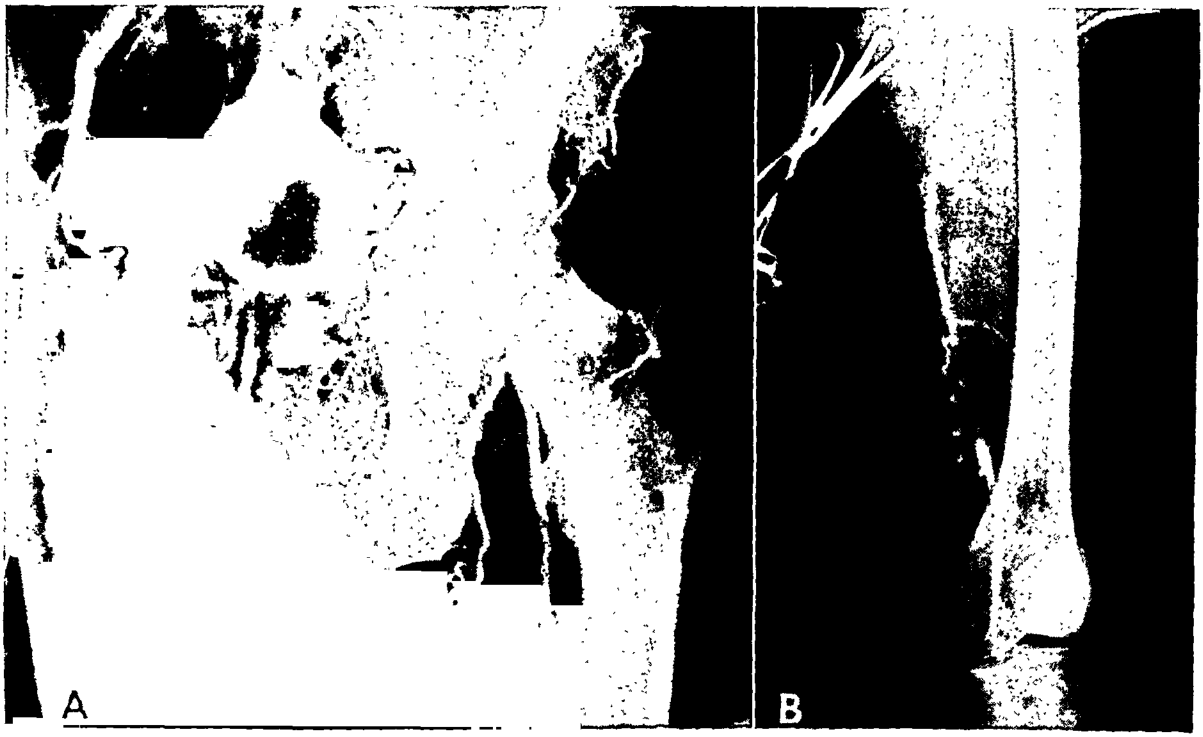

Fig. 5.—*A*, aortogram, showing segmental occlusion of left external iliac artery. *B*, femoral angiogram, showing segmental occlusion of superficial femoral artery.

Results of Arterial Grafting.—From 1954 through 1957 arterial grafting was performed in 348 patients for arteriosclerosis obliterans and in 86 patients for other diseases. Homografts were used in all of the patients. The mean age of the patients at the time of grafting was 51 years; the sex ratio was eight men to one woman. Table 3 summarizes the operative data.

For this discussion the follow-up results include only the cases of arteriosclerosis obliterans. The maximum follow-up time was four and one-half years and the minimum, six months. All of the patients were examined at regular intervals, and a detailed follow-up record was established for each patient.

Of the 348 patients who came to operation 40 had such extensive disease that it was not technically feasible to establish an open graft, but graft procedures were performed in the other 308 patients. Angiograms of most of the 40 patients with inoperable disease indicated extensiveness of the lesions, but it was believed in each case that grafting might be successful and certainly would be worth trying because of the critical condition of the limb.

TABLE 3.—*Summary of Arterial Grafts Performed from 1954 Through 1957*

Disease	Site of Operation	Patients, No.	
Arteriosclerosis obliterans of extremity	Aortoiliac artery	166	
	Femoropopliteal artery	173	
	Renal artery	8	
	Carotid artery	1	
Total			348
Aneurysm	Abdominal aorta	85	
Carotid body tumor	Carotid artery	1	
Total other			86
Grand total			434

Of the 308 patients 22 died in the immediate postoperative period, 9 because of technical failures and 13 from other causes. Thus, 286 patients survived and were available for follow-up study. Results were considered successful in 230 patients who were free of symptoms and had palpable pulses. In the other 56 patients a late shutdown occurred; however, 35 of these patients underwent regrafting and 31 have had a successful result. Of the patients who had regrafting there was evidence of progressive disease distal to the primary graft in 31; this extension of arteriosclerosis was the cause for failure. In the remaining four the cause of late shutdown was in the graft itself. Including the 31 patients with successful regrafts, a total of 261 patients showed satisfactory results. Of the remaining 21 patients 16 were asymptomatic without palpable pulses and 5 were found to have symptoms but refused surgery.

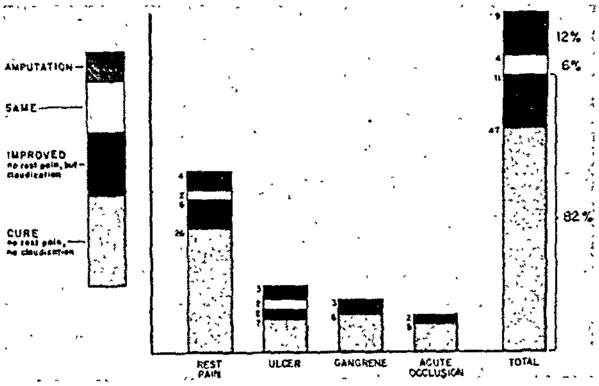

Fig. 6.—Summary of results in patients with severe ischemia undergoing arterial grafting.

In the above series of arterial grafts we included the cases of patients with severe ischemia of the limb. Many of these cases were related to a sudden arterial thrombosis that is secondary to arteriosclerosis obliterans, and others are related to rapid progression of the disease without actual thrombosis in situ but with poor collateral circulation. These patients may have had ulceration or gangrene. Prior to the advent of arterial grafting—regardless of therapy—amputation was inevitable in many cases. Inasmuch as these cases represent a different situation, and are more critical than those in which there is simple intermittent claudication, we have summarized our results separately. Figure 6 summarizes the results in patients with severe ischemia undergoing arterial graft. A total of 71 patients were operated on and 47 had complete relief of symptoms.

In contrast, figure 7 summarizes the results in a similar group of patients who underwent sympathectomy. In this series 66 patients were operated on and 3 had complete relief of symptoms, complete relief being defined as the disappearance of rest pain, and healing of the ulcerative or gangrenous areas. As mentioned previously, we believe that when a patient has evidence of severe ischemia an angiographic study should be made as soon as possible, and if this study indicates that arterial grafting is feasible it should be the preferred procedure.

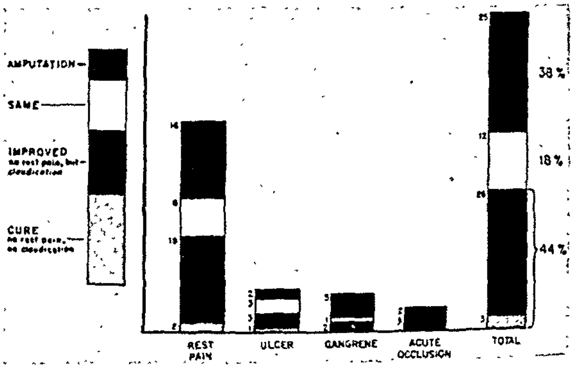

Fig. 7.—Summary of results in patients with severe ischemia undergoing sympathectomy.

Comment

During the past few years much has been learned about the nature and progression of arteriosclerosis obliterans. Until recent years this disease was considered a relentlessly progressive one, whether slow or rapid, and the available medical means of therapy were considered to have little or no effect on the disease. Studies now indicate that this concept is not correct and that approximately 75% of patients with arteriosclerosis obliterans show little progression of the disease over a five-year period. Thus it would seem that any evaluation of medical therapy is handicapped by the fact that some patients improve spontaneously and others remain *in statu quo*. We believe, however, that it is most essential to diagnose these cases early and to advise the patients of the necessity of strict adherence to good hygiene of the feet, protection from trauma, avoidance of extremes of temperature, and non-use of tobacco.

For patients in whom there are signs of progression or definite ischemia as described above, we believe that angiography provides a most desirable method of study. Angiographic study has demonstrated the presence of segmental arteriosclerosis, which may be considered a relatively new concept, inasmuch as patients with evidence of vascular disease were thought to have involvement of a diffuse type. We believe that arterial grafting is indicated, if it is technically feasible as demonstrated by angiography, in patients of the groups described above. Up to the present time, the question of the best material to use in arterial grafting has not been settled, but much work is being carried on in the field of arterial prosthetics, and the future will undoubtedly see improved material become available. We have continued to use homograft material, because it is both available and, in our experience, satisfactory, but we could qualify this statement.

Improvement in techniques continues. It will be noted that in our series there were nine deaths due to technical failure. Seven of those occurred during the first two years and two occurred during the last two years. We believe that the reduction in deaths and failures during the past two years has been entirely related to improvement in techniques as a result of wider experience in the field. We have also noted that when a failure does occur it is usually during the first postoperative year. If a graft remains patent beyond this time there appears to be little chance of its failing, at least in the follow-up time of 48 months in our series. Of our late shutdown failures 35 were in patients who had regrafts and 31 showed evidence of progression of the disease beyond the site of the graft as the cause of the late shutdown. As a general rule, this type of situation occurred in the young patients rather than the older ones. In nonocclusive disease, i. e., aneurysm, there have been no shutdowns.

In a follow-up study of patients after operation, 13 late deaths were recorded. Of these, only seven were due to cardiovascular complications.

Summary

A five-year follow-up study of 500 patients with arteriosclerosis obliterans indicates that the disease may progress and cause disability in one of four patients. Angiography is the only method that demonstrates the presence of the segmental type of arteriosclerosis obliterans, and all patients with severe ischemia, with or without gangrene, should have the benefit of angiographic study in order to determine the feasibility of arterial grafting. In selected cases arterial grafting may be the preferred treatment.

Addendum

Since this paper was presented we have used more than 100 dacron prostheses, in addition to homografts, with comparable early results.

DOG BITES.—The pet animal population in the United States has been increasing rapidly in recent years and, according to Carithers, there are probably about 25,000,000 dogs and 35,000,000 cats in this country. The pleasures of owning pets, particularly dogs, far outweigh the dangers resulting from bites and diseases that animals may cause and the nuisance that they may be in a community. Perhaps these joys and pleasures traditionally cause Americans to resist regulation and licensing of dogs. Accompanying the pleasures which animal pets provide are also the problems of animal bites, rabies, and other diseases transmissible from animal to man. . . .

It has been estimated that approximately 600,000 persons are bitten by dogs each year in the United States; 5 to 10% of the victims have to take antirabies vaccine and about $5,000,000 is spent annually for medical care and public health activity. . . .

Perhaps of greater concern than the cost of dog bite treatment, cosmetic problems due to facial wounds, and the immeasurable loss in wages due to injuries, is the mental anguish that parents suffer when their child is bitten by a dog. This emotional strain is intensified if the dog should happen to be a stray animal in an area where rabies is endemic. The uncertainty of rabies can be a terrifying experience.—Duane Brobst, D.V.M., M.P.H., Henry M. Parrish, M.D., M.P.H., and Frank B. Clack, V.M.D., M.P.H., The Animal Bite Problem, *Veterinary Medicine*, May, 1959.

HEMATOLOGICAL SAFEGUARDS DURING TREATMENT WITH THE PHENOTHIAZINE DERIVATIVES

Anthony V. Pisciotta, M.D., Wauwatosa, Wis.

The phenothiazine derivatives have been of great use in the therapy of mental illness. Any therapeutic agent has potentially toxic properties and the phenothiazines have proved no exception in this regard. The most common toxic manifestations of these drugs, such as drowsiness, emotional disturbances, nasal congestion, Parkinsonism, and dermatitis, have not been considered dangerous as far as the life of the patient is concerned. Jaundice, during phenothiazine therapy, while of lower incidence, is usually self-limited, but permanent liver damage may occur if the drug is continued.

Least common of all reactions, but unquestionably the most serious, is agranulocytosis. This communication deals particularly with the clinical peculiarities of agranulocytosis induced by the phenothiazines and with measures concerned with its possible prevention. Unfortunately, at present there is no reliable laboratory test by which one can accurately predict whether agranulocytosis will follow the use of a drug in a certain individual. Since we do not know the mechanisms which are responsible for agranulocytosis, we have no choice but to establish safeguards on a clinical and, at times, strictly empirical basis.

Agranulocytosis will develop in only a small percentage of persons taking a drug. With certain drugs, such as amidopyrine, this hematological reaction has been attributed to immunological hypersensitivity.[1] In other instances, drug reactions seem to occur because of a possible genetically constituted or acquired abnormality in chemical or enzymatic factors within the blood cells, as yet unknown. This group of blood reactions, peculiar only to a few individuals, is described by the rather indefinite term "toxic," but may be somewhat analogous to the hemolytic reaction attributed to primaquine.[2] Thus, with the thioureas and the sulfonamides, agranulocytosis would not develop before two to eight weeks after the drug was started. In many cases it was of gradual onset and occurred only after large doses of the drug were given which coincided with a possible concentration of the toxic drug in the bone marrow. Frequently, the symptoms of infection did not occur unless the leukopenic reaction had gone unnoticed while the drug continued to be given. What is known of the clinical picture of agranulocytosis induced by the thioureas and the sulfonamides seems applicable to the phenothiazines.

Agranulocytosis followed the administration of chlorpromazine in 18 patients undergoing therapy for mental illness. The total cumulative dose that induced this reaction ranged from 2 to 112 Gm., with an average of 20 Gm. The time required for leukopenia to develop ranged from 10 to 400 days, but in most cases it was recognized after 20 to 45 days of therapy. It was found in highest incidence in women and only in Caucasian patients. During prolonged periods of treatment with this drug it was impossible to predict when a sudden drop in the leukocyte count would occur. When phenothiazine derivatives are used in treating chronic mental illnesses, it is considered essential that weekly leukocyte counts be made, especially between the 2nd and 10th week of treatment; that monthly counts be made thereafter as long as the patient continues to receive the drug; and that observers be instructed to report promptly all instances of sore throat, stomatitis, fever, malaise, chills, or other evidences of infection.

Clinical and hematological study of 18 patients with agranulocytosis induced by chlorpromazine and those reported by others has disclosed a number of peculiarities which may provide clues relative to the nature of the reaction and its possible prevention. These were described in detail in another communication.[3] These experiences have not been sufficiently extensive to withstand critical analysis, but some limited generalizations may be made at this time. It has been found that agranulocytosis is of greatest incidence in Caucasian women and to the present writing is not known to occur in Negroes, except for an occasional instance of moderate leukopenia in Negroes on therapy with huge doses of chlorpromazine. With few exceptions, it has occurred almost exclusively in mentally ill patients despite the widespread general use of the drug in clinical practice. The most likely reason for this is that the mentally ill are more likely to receive larger doses of the drug over a long period of time. There is a remote possibility, however, of a chemical or enzymatic abnormality peculiar to mental illness, which might result in an increased susceptibility to agranulocy-

tosis. In susceptible individuals, the clinical occurrence of agranulocytosis induced by phenothiazines appears to depend on dose of drug and length of time it is administered. In our series, agranulocytosis occurred after a total cumulative dose of 2 to 112 Gm. of chlorpromazine, with an average of 20 Gm. The time required for leukopenia to develop was 10 to 400 days after phenothiazine therapy had been started, but most cases occurred after about 20 to 45 days of therapy. The pattern of development of agranulocytosis has been studied in susceptible patients during sustained treatment with a high dose of the drug. During the period of incubation, the leukocyte count may show no change, but in some individuals there is a tendency to a gradual diminution in the number of white blood cells. When agranulocytosis occurs, there is a sudden drop in leukocytes, which reach their lowest point in two to five days. At this time, the bone marrow shows a highly selective aplasia of all granulocyte precursors. At the beginning of agranulocytosis, no symptoms and no infection may be present so that routine blood cell counts are necessary for the early diagnosis of this hematological reaction. If treatment with phenothiazine is continued, infection will almost certainly develop, manifested by fever, pharyngitis, proctitis, and septicemia. If the drug is withdrawn, recovery usually occurs within 5 to 10 days, provided the patient does not die from infection.

The effects of readministration of the drug were reported by Yules and Baker[4] and by me and my associates.[3] One woman, given chlorpromazine in lower dosage, showed no subsequent hematological reactions, even after a year of follow-up examinations. Another woman, who had agranulocytosis induced by chlorpromazine (Thorazine), developed agranulocytosis a year later after a month of treatment with promazine (Sparine), and, one year after this episode of agranulocytosis, developed it again one month after continuous administration of prochlorperazine (Compazine).

Protective Measures

The following clinical observations form the basis for the protective measures during therapy with phenothiazine derivatives which are presently employed at the Milwaukee County Hospital for Mental Diseases. It is understood that some of these recommendations are subject to change, pending additional experience with this type of blood reaction during therapy with phenothiazines.

As with any drugs with potential side-effects, it is recommended that administration of the phenothiazine derivatives, especially in high dosage, sustained over a period of several weeks, be carried out only if the clinical indications are sufficiently clear-cut to warrant the risk entailed. When used, the smallest amount to give the desired clinical effect should be given.

Because the onset of agranulocytosis is generally later than 10 or 20 days after beginning of treatment, rigorous hematological controls may not be necessary during short-term (i. e., less than two weeks) administration of small amounts (less than 75 mg. daily) of chlorpromazine. Even at that, it would be desirable to get a leukocyte count at the beginning and at the end of short-term therapy. On the other hand, the prolonged or permanent administration of the drug requires that weekly leukocyte counts be made, especially between the 2nd and 10th week of treatment. Thereafter, a monthly leukocyte count should be made as long as the patient continues to receive the drug. Even then, this is not regarded as entirely safe, as a sudden drop in the leukocyte count may occur at any time.

Great reliance should be placed on clinical observation of the patient during time of treatment with phenothiazine by nurses, attendants, and physicians acquainted with the clinical manifestations of agranulocytosis. Observers should be instructed to report promptly all instances of sore throat, stomatitis, fever, malaise, chills, or other evidences of infection.

If the leukocytes show a gradual drop, the stained smear should be studied when leukopenia occurs. In agranulocytosis, one expects to see an absolute fall in the number of neutrophilic stab forms or segmented cells and a predominance of mature lymphocytes. The drug should be withdrawn if the total leukocyte count falls under about 3,500 per cubic millimeter or if the total number of neutrophilic granulocytes represents less than 30% of the differential count. A leukocyte count between 3,500 and 4,000 per cubic millimeter and granulocytes between 30 and 50% require daily observation while the drug is being continued. A sudden drop in leukocyte count from a normal to leukopenic levels (less than 3,000 per cubic millimeter) within one week necessitates that the drug be withdrawn immediately and the patient isolated and placed on protective therapy with antibiotics. It would be useful to examine the bone marrow in case of doubt or at the height of agranulocytosis, as granulocytic aplasia or hypoplasia is a characteristic finding.

The fact that agranulocytosis occurs in men, despite its lower incidence, makes it necessary to apply these precautionary rules during the time men are treated with the phenothiazine derivatives. We may consider that while Negroes show a diminished susceptibility to this drug, the possibility of agranulocytosis demands that patients of this racial group have periodic leukocyte counts if they are receiving daily doses of phenothiazine which exceed 100 mg. for a period greater than two weeks.

Despite the observations that chlorpromazine may be readministered to a susceptible patient without the immediate recurrence of the disease, it is unwise to treat any person recovered from phenothiazine-induced agranulocytosis with the same or related drug.

HAZARDS TO THE HOST OF BENIGN INTRATHORACIC TUMORS

Richard H. Overholt, M.D.
and
Wilford B. Neptune, M.D., Boston

The tumor hazard to the host depends on two factors: the location of the lesion in relation to vital structures and the cancer potential. Correlation of clinical data (history, physical findings, roentgenograms, endoscopy, cytology, function tests, and living surgical pathology) now permits a more accurate appraisal of the two risks. The hazard of benign intrathoracic tumors is dependent on their location in relation to tube structures of the upper mediastinum and the potential threat of malignancy. During the past three decades, exploration of the thoracic cavity has become a common event in many hospitals. The act which establishes the diagnosis, i. e., total biopsy, provides simultaneously curative therapy. Hazards to the host of benign tumors greatly exceed the risk of their removal.

The presence of a new growth anywhere in the body calls for an estimate of risk. One must balance the potential threat of the lesion itself with the risk of treatment. The tumor hazard to the host depends on two factors: the location of the lesion in relation to vital structures and the cancer potential. The risk of excising the tumor is determined, to a considerable extent, by these same factors plus the experience of the surgical team.

During the past three decades, exploration of the thoracic cavity has become a common event in many hospitals. Correlation of clinical data (history, physical findings, roentgenograms, endoscopy, cytology, function tests, and living surgical pathology) now permits a more accurate appraisal of these two risks—that imposed by the tumor and that of treatment.

Most mediastinal tumors are benign; most intrapulmonary tumors are malignant. (Tumors of lymphatic origin are excluded, since they must all be considered as malignant.) Regardless of histological classification, either type may be lethal. Death is usually not produced because of the implication of the lung, per se. One lung may be totally destroyed or compressed and yet the other still sustain life. The crowding within the mediastinum caused by an expanding benign tumor or a metastatic pulmonary cancer is responsible for most deaths. The location of a growth within the area of such vital tubes as superior vena cava, azygos and innominate veins, carotid arteries, trachea, and esophagus makes possible the obstruction of one or more of these structures before the heart or lung is overwhelmed.

The rate of expansion has a bearing on risk. If serial x-rays over a period of several years are available, some estimates of past growth can be obtained. Unfortunately, they do not indicate future behavior.

Read before the Section on Diseases of the Chest at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

A Dangerous Site

Benign mediastinal tumors take origin from the various tissues of the area. Histological types have their sites of predilection. The four quadrants of the mediastinum serve as a useful way to group them. The most common tumors are indicated in figure 1.

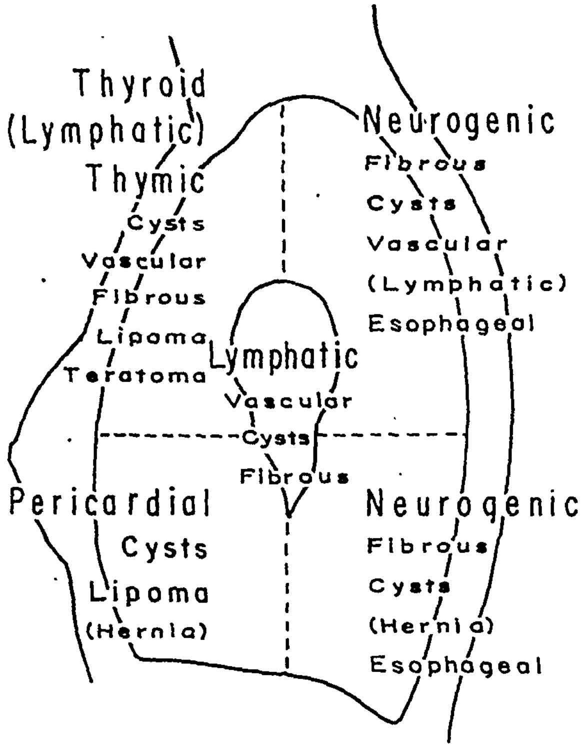

Fig. 1.—Most common location of mediastinal tumors. Although thymic and lymphatic tumors are listed, we consider all such tumors malignant. Also, hernias are shown, since they present tumor-like shadows.

Tumors arising posteriorly in the paravertebral sulcus in either the upper or the lower part of the thorax are not strictly within the mediastinum. They are situated lateral to vertebral bodies and mediastinal pleura. They expand in the direction of the lung and at the expense of its volume. They may attain great size without producing symptoms or disturbing pulmonary function to a noticeable degree. Pressure on intercostal nerves may cause pain. Their greatest hazard is to the central nervous system, for they may grow within a vertebral foramen and compress the spinal cord.

Superior mediastinal tumors are in the most dangerous position of all. If centrally placed beneath the manubrium they become wedged between it and the vertebra and expansion must be in a lateral direction. Tubular structures are displaced or compressed (fig. 2 and 3). The tracheal rings will resist pressure longer than vascular tubes. The trachea usually becomes displaced far to the right or left long before its lumen is reduced in diameter. The esophagus, having a muscular tube whose walls are normally in apposition except during acts of deglutition, also suffers displacement but hardly ever is obstructed by an expanding benign tumor. Occlusion of the esophagus rarely takes place except when its mucosa has been invaded by a malignant tumor or there is circumferential cicatrization of its wall as a result of infection or trauma.

Lower anterior tumors have little room in which to expand. The roof (sternum) and the floor (heart) do not yield to the pressure of tumor expansion. The density of the heart and its constant motion prevent growth in that direction. Tumors taking origin in this area push to one side or the other, rarely both. The lung suffers most of the volumetric loss as these tumors grow. In advanced states, there may be cardiac displacement or compression.

The majority of benign tumors taking origin within the lung do not disturb its function until they have attained great size. The most common, hamartoma, usually grows slowly and silently at some distance from a major bronchus or tangential to it. Rarely is a bronchus obstructed. Usually, important vascular structures escape impingement. Bronchial adenomas and papillomas do cause serious trouble, not because of displacement of vital structures but because they often occlude the bronchus at their site of origin. Most of the host disturbance results from secondary infection and the effects of the bronchial occlusion.

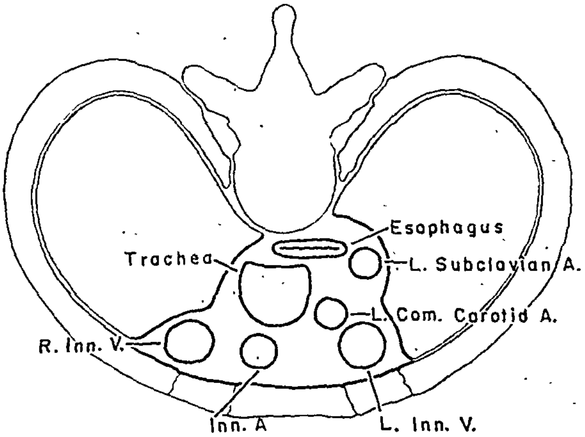

Fig. 2.—Cross section of upper part of the thorax. Vital structures within mediastinal area are shown.

Paradox of Shadow Density

There are no absolutes in nature. This is true for the growth characteristics of various tumors and also for their roentgenographic shadows. The more dense, clear-cut, and undisputed the x-ray evidence, the more ominous and threatening the lesion appears to many physicians. Shadows with densities of great contrast seem to evoke immediate consideration for action. Top priority is given to neoplastic possibility. The paradox of shadow density is that risk is usually inversely related to degrees of density. Hazy, ill-defined disputable areas of altered density do, in fact, represent lesions carrying a far more serious import than the circumscribed, dense, "easy-to-see" shadow. This paradox applies particularly in asymptomatic cases.

In an asymptomatic 67-year-old nonsmoking woman a chest film showed an ill-defined area of density in the upper right part of the lung field, with a questionable central zone of rarefaction (fig. 4*A*). Cytological, bacteriological, and skin tests were negative. This vague x-ray finding proved to be the most serious of all those illustrated in this article. The other shadows are denser, more clear-cut, and apparently more ominous. Yet this was the shadow of a cancer; the others were of benign lesions.

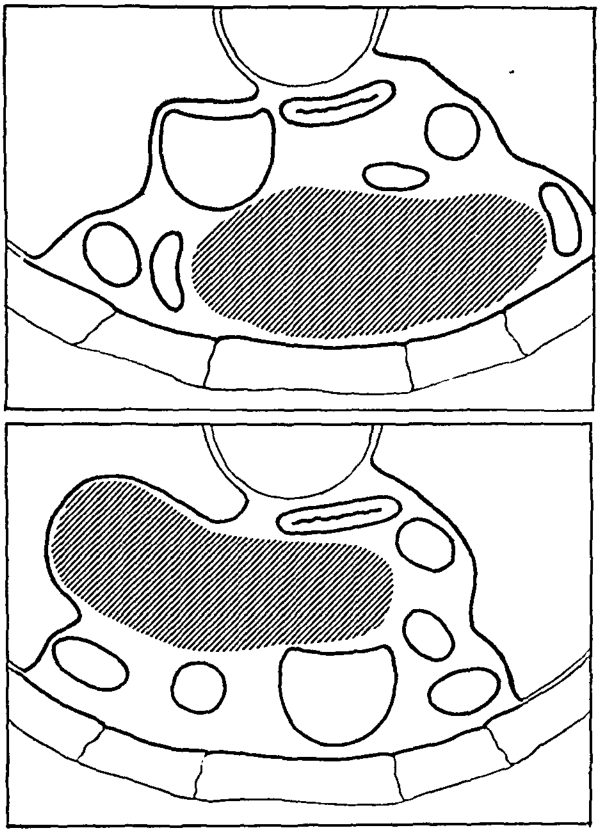

Fig. 3.—Cross sectional drawings of mediastinum, illustrating displacement and compression of tube structures as result of benign tumor expansion in this area.

Calcium as an Age Indicator

Risk can be more accurately appraised if the future behavior of a neoplasm can be foretold. Fortunately, a few intrathoracic lesions become calcified. The presence of such deposits in all parts of the area of density is a very reliable "built-in" age indicator. Their growth must have terminated when the calcium salts were precipitated within them.

If a calcific tumor does not cause symptoms or disturb function of neighboring structures, it may remain indefinitely without great risk. Larger, stationary tumors may, by space occupancy, reduce pulmonary reserve to a critical level. Then, the slight risk of removal would be well balanced by the advantages of increasing cardiopulmonary reserve.

A large calcified tumor was found on a chest film in a 48-year-old asymptomatic woman (fig. 4*C* and *D*). The size, shape, and character of the shadow has not changed since the discovery film, 10 years previously. Its space occupancy reduces the functional capacity of the left lung proportionately, but this is not a serious hazard.

The factor of safety, implied by the presence of calcium, does not apply if there are two components of the area of density, one with and one without calcification. Cells capable of growth may be present in the "soft" area. The hazard to the host of this component, considered separately, must then be weighed against the risk of excisional therapy.

Balancing Risks

Individual patients with benign tumor problems are not helped much by statistical analysis of large groups of figures. It is important, however, to know which risk is the greater, that imposed by the tumor or that of treatment. No estimate of the hazard of continued growth of benign tumors is possible. In fact, one is not able to make an absolute diagnosis of a shadow. The growth pattern of those lesions which have been removed is interrupted by the act which establishes identity. It is, therefore, impossible to provide control series of like cases. However, the cancer potential of intrathoracic tumors can be gauged from collected series of excised lesions. The proportion of malignancy in intrapulmonary tumor-like shadows exceeds 20%. Davis and others[1] state that 36% of 1,203 of a collected group of solitary pulmonary nodules were malignant. In a collected series of 396 mediastinal tumors (excluding those of lymphatic origin), Ringertz and Lidholm[2] report a cancer incidence of 11%.

The risk of exploration and removal of intrathoracic tumors comes well below the risk of the lesions in both categories. In our experience, the operative mortality in the past five years has been less than 1% for all mediastinal tumors and less than 1% for benign, intrapulmonary tumors. (During the past five years 128 patients with tumor-like shadows have been treated by intrathoracic exploration and excision for nonmalignant conditions. There was no operative mortality. It seems reason-

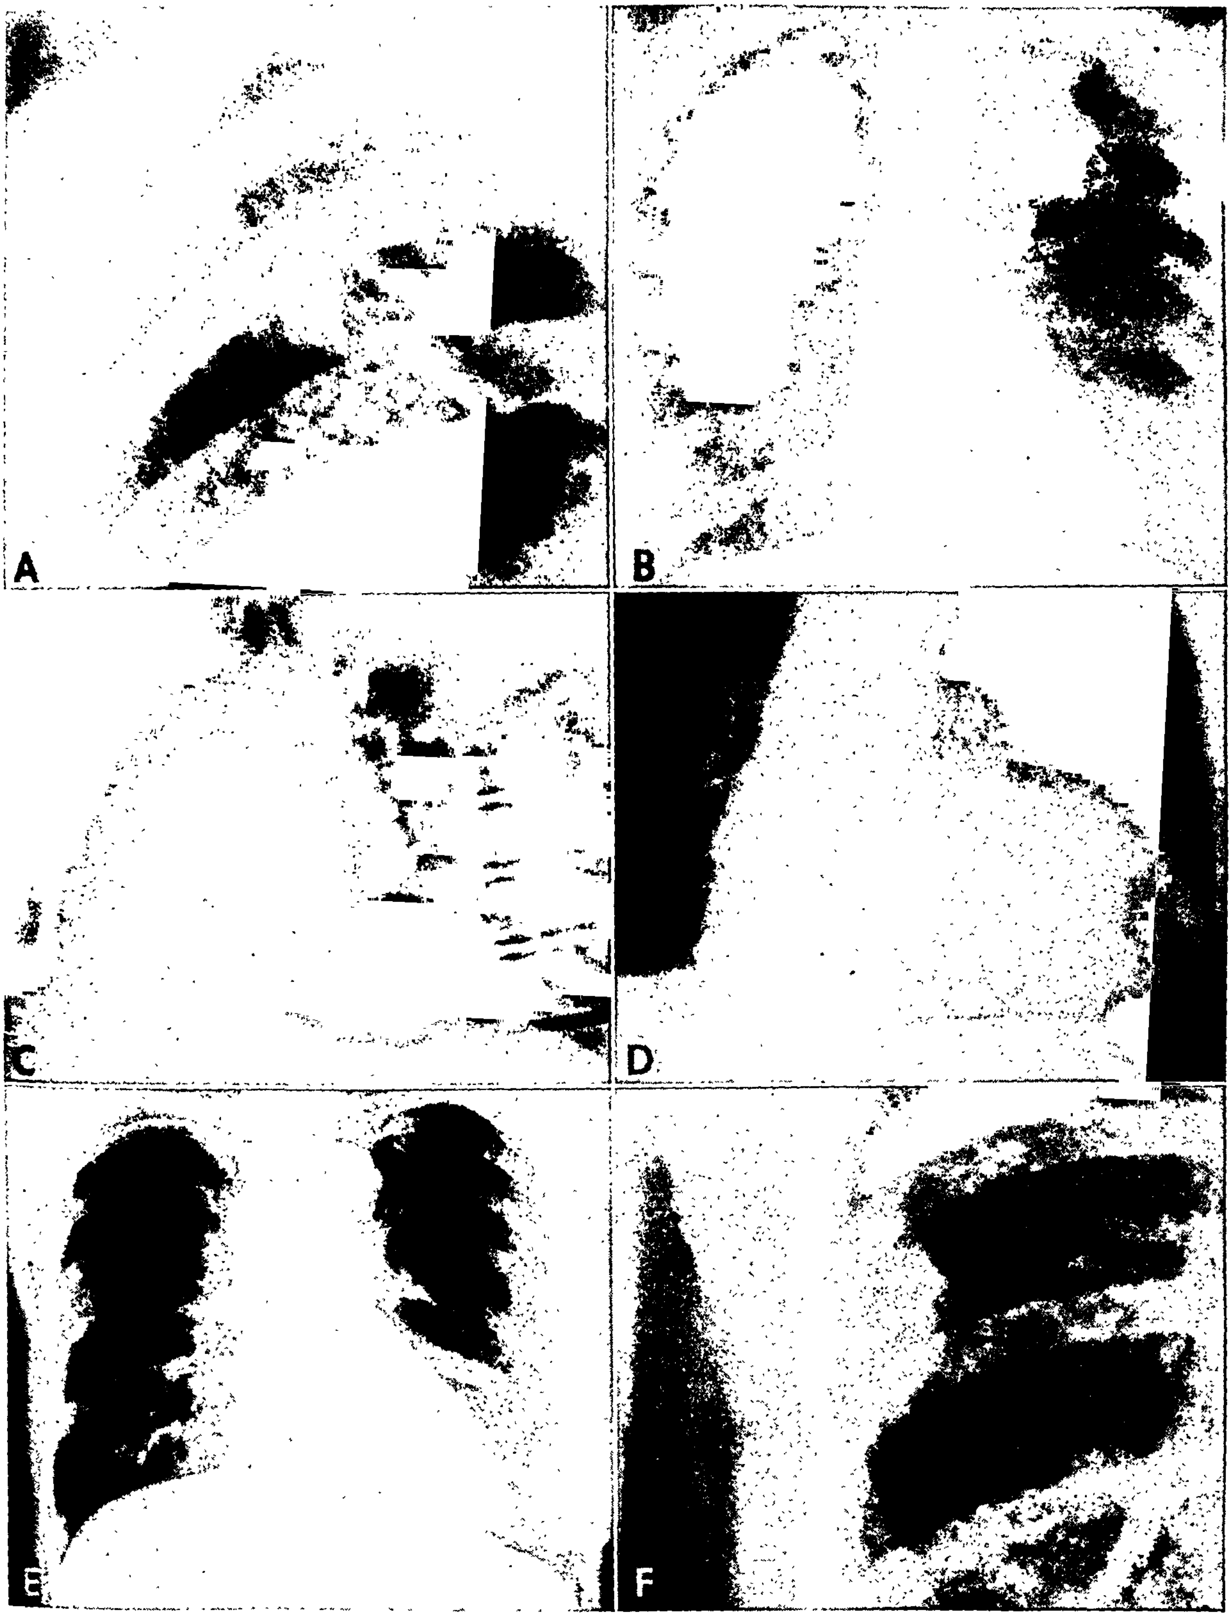

Fig. 4.—*A*, ill-defined area of density with questionable central zone of rarefaction in spot film of upper part of right lung field in asymptomatic 67-year-old nonsmoking woman. Vague x-ray finding proved to be most serious of those illustrated; this was shadow of cancer. *B*, chest film revealing large, irregular area of great density in upper third of left lung field. This lesion proved to be intrapulmonary and benign (hamartoma). *C* and *D*, chest films revealing large calcified tumor in asymptomatic person. Size, shape, and character of shadow has not changed since discovery film, 10 years previously. *E*, x-ray taken two years after removal of patient's right breast for carcinoma. *F*, spot film from same case, showing rib detail with evidence of altered contour of seventh rib. Lesion plus rib was completely excised for total biopsy. Lesion proved to be benign schwannoma taking origin from intercostal nerve.

able to place the calculated risk for surgical treatment of benign lesions at a figure which is less than 1%.)

Single Act for Verification and Treatment

By their very nature and location, most benign intrathoracic tumors do not yield to a precise preoperative histological diagnosis. Bronchoscopy, cytological examination of bronchial secretions or pleural fluid, or cervical-node biopsy fails to settle the issue. Intraluminal bronchial tumors may be an exception. Rarely does information obtained by transthoracic needle biopsy aid in patient management. If resection is possible, such a preliminary keyhole approach adds a risk with no counterbalancing benefit. Aspiration of material from a large peripheral tumor might be justified in patients who are obviously inoperable. The exact identity of noncalcified intrathoracic neoplasms is preferably determined by total biopsy. It is a rare benign tumor which cannot be completely and safely extirpated. Many malignant lesions can be totally extirpated as well. If a lesion is malignant and unresectable, a partial removal or adequate biopsy yields important information to gauge radiation or chemotherapy.

The decisive step necessary to establish the diagnosis, therefore, becomes for most cases the curative procedure. Discovery and localization are accomplished by a single act—radiography. Diagnosis and treatment are also one procedure. When risks are weighed and the patient is advised as to the best course to follow, management can be direct, simplified, and safe.

In a 40-year-old woman a chest film revealed a large, irregular area of great density in the upper third of the left lung field (fig. 4*B*). This shadow-producing lesion proved to be intrapulmonary and benign. It was a hamartoma. Total biopsy by lobectomy proved to be curative.

Two years after removal of her right breast for carcinoma, a 46-year-old woman had evidence on a spot film of altered contour of the seventh rib (fig. 4*F*). The lesion plus the rib was completely excised for total biopsy. The lesion proved to be a benign schwannoma (neurolemoma) which took origin from the intercostal nerve. This diagnostic act simultaneously became the curative procedure.

Approaches

Intrathoracic exploration has advantages over exploration in other areas. A single organ, the lung, occupies this large body cavity. It can readily be deflated to permit a clear view of all areas. The mediastinum may be widely exposed from either side or from above.

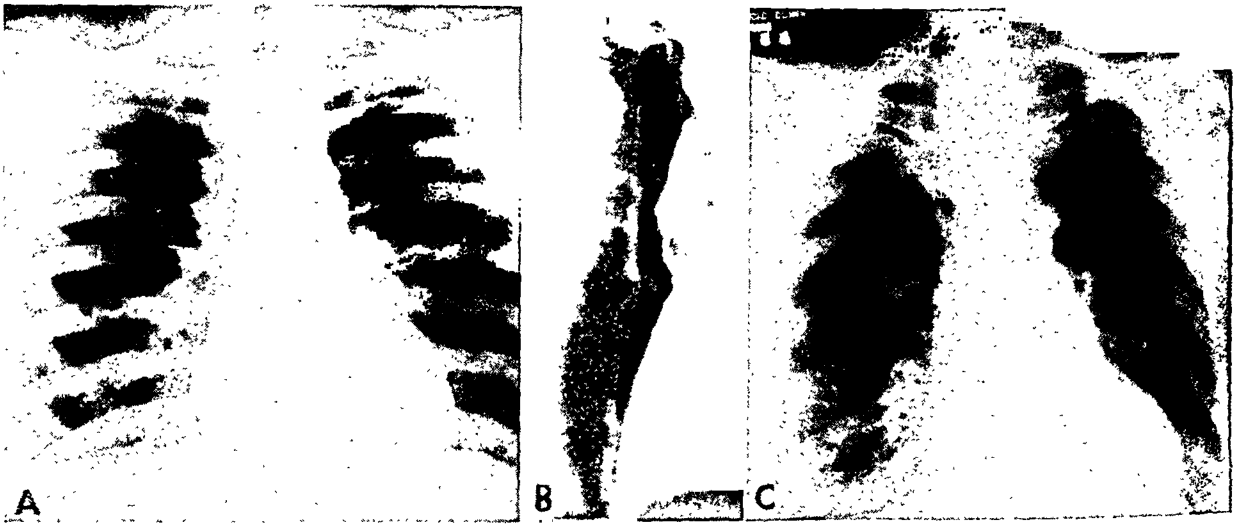

Fig. 5.—*A*, x-ray revealing widened upper mediastinal area in patient with substernal distress and mild dysphagia. *B*, esophagram from same case, showing distortion and luminal dilatation. At thoracotomy large mass was found involving esophagus, with forward displacement of trachea and great vessels. Tumor proved to be benign leiomyoma. *C*, chest film illustrating most common of all benign intrathoracic tumors, goiter. Note marked deviation of trachea.

The intrathoracic space can be approached in various ways, depending on the tumor site. A posterolateral incision with the patient in the prone position is used for most highly placed tumors or for those which will probably require segmental or other types of lung resection. For low lesions, an anterior incision placed below the breast is frequently chosen. Rarely is a sternal-splitting incision or transection required, even for large mediastinal tumors which bulge both ways. The sternum is a narrow structure, and the area below it can be widely exposed transpleurally from either side. This avoids disruption of the central support.

Most benign tumors within the mediastinum can be clearly enucleated without injury to neighboring structures. After the mediastinal pleura is divided and the proper plane of separation is developed, a finger can be passed over or under the tumor to the opposite side. Then counterpressure dislocates the tumor into the operative area. The blood supply is secured, and the tumor is quickly extracted.

Usually, a benign tumor within the lung can be enucleated easily without loss of lung substance. Some may require a subsegmental resection. Rarely need a lobe be sacrificed.

The osseous cage itself can be reconstructed securely. Ribs are never resected unless they are involved with the tumor. The ends of severed ribs or cartilages can be firmly reunited. When the lateral shafts of ribs are being anchored, sutures can be placed through punch holes to avoid intercostal nerves. The precise reapproximation of fascia, muscle, and skin layers eliminates or minimizes postoperative discomfort; convalescence is speeded, and the total period of disability is shortened.

X-ray in a 34-year-old woman who had substernal distress and mild dysphagia revealed a widened upper mediastinal area (fig. 5*A*). An esophagram showed distortion and luminal dilatation (fig. 5*B*). At thoracotomy a large mass was found involving the esophagus, with forward displacement of the trachea and great vessels. The tumor was sausage-shaped, 4 cm. in diameter and 10 cm. in length. The muscle coat of the esophagus was markedly thinned out, but the mucosa was not involved. Enucleation was accomplished without injury to the mucosal tube. All symptoms were relieved, and the patient remained well. This tumor proved to be a benign leiomyoma.

In a 62-year-old woman who complained of cough and severe dyspnea a chest film revealed a goiter (fig. 5*C*), the most common of all benign intrathoracic tumors, and marked deviation of the trachea. Veins of the neck were distended, indicating superior vena caval obstruction. The possibility of a carcinoma of the thyroid was entertained. At exploration, with the cervical approach, a benign, nodular goiter was removed from the superior mediastinum. The obstruction of the tubular structures of the area was immediately relieved. The patient has remained well.

Summary

The hazard to the host of benign tumors is dependent on their precarious location in relation to tube structures of the upper mediastinum and the potential threat of malignancy. A paradox of roentgenographic interpretation exists in many cases; the less dense or ominous the appearance of the shadow, the more serious is the substance that has produced the shadow. An indication of the age of the lesion may be provided by calcific deposits within it.

The act which establishes the diagnosis, i. e., total biopsy, provides simultaneous curative therapy. Hazards to the host of benign tumors greatly exceed the risks of their removal.

MALIGNANT CARCINOID.—The pathological entity of carcinoid tumors is well recognized. They are encountered in the gastrointestinal tract from the cardia to the rectum, being seen most frequently in the appendix (70 per cent), the rectum (10 per cent), and in the terminal ileum. In the small bowel, the incidence of malignant behavior ranks as high as 25 to 50 per cent. Many of these carcinoid tumors with extensive metastases act as an endocrine neoplasm and produce a peculiar syndrome. . . . The presence of a functioning carcinoid tumor should be suspected not only when the entire syndrome is present but whenever any single sign or symptom is encountered. Valvular heart disease, hepatomegaly, hot flushes, chronic diarrhea, and so forth, are worth more critical investigation. A malignant carcinoid tumor should also be considered in patients with metastatic neoplasms who have an unexpectedly benign and prolonged course. . . . Any surgeon faced with a malignant intestinal neoplasm having regional or distal spread should rule out the possibility of a carcinoid before deciding upon a bypass procedure. Because of the slow growth of both primary and metastatic argentaffinoma, and also because of the serious ill-effects of excess serotonin, every effort should be made to remove as much of the tumor tissue as is technically and safely possible. Carcinoid tumors should no longer be considered benign.—Pierre Grondin, M.D., M. E. Donley, M.D., Tirso Del Junco, M.D., D. E. Ross, M.D., Malignant Carcinoid Syndrome, *Western Journal of Surgery, Obstetrics and Gynecology,* November-December, 1958.

CLINICAL NOTES

TORSION OF THE GALLBLADDER

Sadredin Musavi, M.D
and
George H. Yeager, M.D., *Baltimore*

Wendel[1] reported the first case of acute torsion of the gallbladder. To date, 112 cases of torsion of the gallbladder have been collected from the world literature. In only two cases was a correct preoperative diagnosis made.[2]

Report of a Case

An 82-year-old woman was admitted to University Hospital on Dec. 22, 1956, because of the sudden onset of right-sided abdominal pain about 30 hours prior to admission. The pain was associated with nausea and bile-stained vomit. The patient had had gallbladder disease 10 or 15 years ago. Four years prior to this admission, at another hospital, a cholecystogram and gastrointestinal x-ray studies were made, results of which are said to have been normal except for gastroptosis.

The patient was hypasthenic, with marked thoracic kyphosis. She was moderately dehydrated. The pulse was 100 per minute; blood pressure, 150/80 mm. Hg. Rectal temperature was 101 F (38.2 C). She appeared acutely ill. The right side of the abdomen was exquisitely tender. The rest of the abdomen was soft. There was no distention and no abdominal masses could be defined. Proctoscopic and pelvic examination revealed no abnormality.

Results of laboratory studies were as follows: hemoglobin level, 14.5 Gm.%; leukocytes, 17,500 per cubic millimeter; hematocrit value, 45%; blood urea nitrogen level, 30 mg.%; carbon dioxide–combining power, 20 mEq. per liter. Urinalysis showed normal findings except for traces of acetone and albumin.

The preoperative diagnosis was acute cholecystitis. After satisfactory hydration the patient's abdomen was explored. A moderate amount of serosanguineous fluid was encountered in the peritoneal cavity, mainly in the right gutter. The fluid had a feculent odor. The gallbladder was distended, dark purple in color, and hanging on a pedicle, which was obviously the cystic duct and artery. There was positive (clockwise) torsion of the gallbladder on this pedicle through 360 degrees. The gallbladder was removed with ease. The peritoneal fluid was evacuated and the subhepatic space drained. The gallbladder contained about 25 cc. of bloody, bile-stained material but no stones. Culture of the gallbladder contents revealed Escherichia coli. Histological examination of the gallbladder wall revealed early necrosis. The patient's condition during the first two postoperative days was somewhat uncertain, but her recovery was complete, and on the eighth postoperative day she was discharged from the hospital.

Comment

Since Wendel's report in 1898, 112 cases[3] of torsion of the gallbladder have been reported. The physical findings are not pathognomonic. Short and Paul,[4] in describing a case, suggested that if there is a mass in the gallbladder region which appears and disappears torsion and untwisting of the gallbladder should be suspected. Most patients whose cases have been reported have been women past middle age. Of 106 cases in which the age of the patient has been recorded 77 patients were over 50 years of age, including 14 patients over the age of 80 and 4 over 90. Wendel's case was that of a 23-year-old woman and is the only case of torsion with perforation on record.

Gross[3a] postulated that in the later decades of life supporting adipose tissue largely disappears from the surrounding structure, and atrophy of these tissues allows for greater ptosis of the viscera, including the floating gallbladder. Konjenzy[5] incriminated congenital ligamentous structures in the right upper quadrant causing strangulation of the floating gallbladder. Caldwell[6] suggested that a tortuous arteriosclerotic cystic artery may encourage rotation of the organ. Rais and Thulin[3b] proposed that altered position of the abdominal organs due to kyphoscoliosis might contribute to the development of torsion. Despite the large incidence of torsion of the gallbladder in elderly patients not all cases occur late in life. Cuervo[7] reported two cases. His first patient, a 5-year-old boy, survived. His second patient, an 11-year-old boy, died after delayed intervention. Stones have been reported in only 31 recorded cases.

It is obvious that a gallbladder which is completely surrounded by peritoneum and lies free in the peritoneal cavity, or one with a mesentery, is susceptible to torsion. The incidence of such anatomic relationship of the gallbladder is reported to be between 1 and 5%. Peristaltic activity of the

transverse colon and duodenum, violent movement of the body, or a sudden fall have been thought to initiate torsion.[8]

Symptomatic, intermittent, partial torsion of the gallbladder is not recognized as a clinical entity by most surgeons. Certainly there are very few reported cases of cholecystectomy for this condition. Short and Paul[4] quote Fischer of Budapest, who described two patients, both women, aged 44 and 29, with recurrent and incomplete torsion of the gallbladder. Both patients had visceroptosis and the torsion was through 90 degrees in both. Although stones were present in both, one patient had a cholecystectomy and the other had her gallbladder anchored with sutures. Krukenberg[9] is reported to have described two patients in whom kinking of the gallbladder gave rise to attacks of colic. In each instance the gallbladder was found to be long and acutely flexed on itself.

Summary

Complete torsion of the gallbladder in an 82-year-old woman was treated successfully, although not diagnosed preoperatively. A total of 113 cases, including the one recorded here, have been reported to date.

University Hospital (Dr. Yeager).

UNUSUAL FOREIGN BODY (STEINMANN PIN) IN BLADDER

Raymond J. Fitzpatrick, M.D., Gainesville, Fla.

Any solid material small enough to pass through the external urethral meatus may set up permanent residence in the urinary bladder. Most foreign bodies lost in the bladder have been self-introduced. Krugman and Rieser[1] reported a case of a thermometer lost in the urinary bladder by a patient who was taking vaginal temperatures to determine the time of ovulation. I recall an elderly patient who attempted dilatation of his urethral strictures with use of a wire coat hanger to the end of which was insecurely affixed a 3-in. length of wooden crayon. The wooden crayon, encased in stone, was surgically removed several months later.

Despite the degree of frequency with which orthopedic "hardware" is used in and about the hip, the orthopedic surgeon has rarely encroached by inadvertence on the urologic field. In 1936, Grant[2] reported a case of a beef-bone peg migrating into the urinary bladder of a woman patient four months after it was used in pinning an intracapsular fracture of the left femur. In 1947, Branham and Richey[3] reported a partial penetration of the left lateral wall of the urinary bladder by a Kirschner wire two months after it was used in pinning a fracture of the left femur. McCrea, cited by Branham and Richey, reported the penetration of the prostate gland by a large screw driven through the left acetabulum in an effort to pin a fractured hip. The following case has unusual features which make it worthy of reporting.

Report of a Case

An unmarried woman, aged 20, seven months pregnant, was admitted to the hospital on Sept. 20, 1957, for removal of a foreign body from the bladder. In the second month of pregnancy she began to have a constant dull ache in the suprapubic region, associated at times with burning and frequency of urination but almost always accompanied by sharp, knife-like pain at the end of urination. On each prenatal visit the family physician found pyuria, for which "broad-spectrum" antibiotic therapy had been tried without success. No other complaints were offered. The patient denied having fever, hematuria, or dyspareunia. Her history was unremarkable save for a period of hospitalization seven years previously for "pain in the left hip." The patient's memory of the illness was vague; she denied having undergone an operation but could recall that she had been "put to sleep" and that "the hip was put back in place." She subsequently developed a limp due to shortening of the left leg.

At examination the only unusual finding was a fused left hip. Urinalysis revealed numerous pus cells and 2+ albumin value. Cystoscopic examination with bladder fully distended revealed a long silvery nail-like object lying free in the bladder. The caudal end was encased in a large white calculus, as demonstrated in figure 1. The cranial end was pointed, and along the dome of the bladder five areas of superficial ulceration were observed which suggested that the cranial end of the metallic foreign body altered position from time to time. No vaginal discharge was noted on pelvic examination. The distal third of the metallic object and the stone could be palpated.

Confirmation was sought of the clinical suspicion that the metallic object had arrived at its destination through inexpert efforts to induce abortion. The patient denied that any such attempt had been made but did admit to consuming in early pregnancy an unknown quantity of liniment when advised by friends regarding its ecbolic efficacy. All she induced, however, was an upset stomach. Since one could readily visualize rupture of the bladder should labor start, the patient was advised to enter the hospital without delay for removal of the foreign body.

The patient's mother asked if it were possible for a piece of metal to travel from "the hip bone into the bladder." The mother stated that seven years previously, on Aug. 18, 1950, an open surgical procedure had been performed on the daughter's left hip, contradicting the daughter's previous denial of having had an operation. The mother also stated that four months postoperatively a piece of metal emerged from the outer aspect of the patient's left mid-thigh. Further examination revealed a fine scar on the posterolateral aspect of the left hip which had been missed when the patient was examined in the draped lithotomy position. A roentgenogram of the abdomen (fig. 2) revealed the orthopedic pin present in the bladder and one small pin still present in the left hip. The original films made after the hip-pinning were unfortunately not available for study.

On Sept. 23, 1957, the bladder was opened through a low transverse suprapubic incision. A Steinmann pin, 9.5 cm. in length and partially encrusted by a stone measuring 4 by 3 cm. in diameter, was found lying free in the bladder cavity. Some fibrous thickening was noted in the paravesical tissues, suggesting that the pin had burrowed its way through the acetabulum into the bladder. The patient had an uneventful postoperative course. The urethral catheter was removed on the fourth day, and the patient was discharged on the fifth postoperative day. A follow-up cystoscopic examination on Oct. 7, 1957, disclosed only mild residual trigonitis. The patient had an uneventful delivery on Dec. 11, 1957.

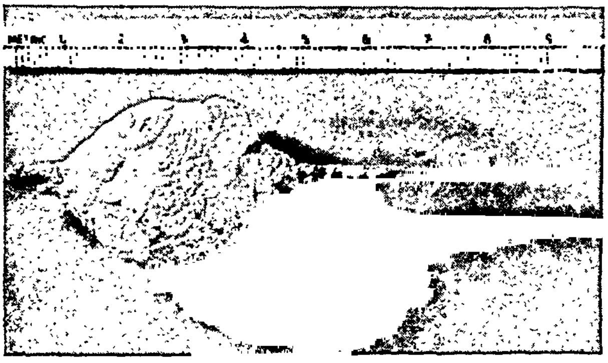

Fig. 1.—Steinmann pin removed from bladder.

Comment

The symptoms of a foreign body in the urinary bladder are basically those of any urinary bladder calculus. Symptoms may be delayed after introduction but are usually constant once begun. Pain is usually present and is often most severe when the patient is expressing the last few drops of urine. Dribbling and sometimes complete urinary obstruction cause the patient to seek medical help. If the foreign body is self-introduced feelings of guilt or shame may cause the patient to delay seeking medical help until the symptoms become totally unbearable. When the foreign body invades the bladder wall from without, extravasation frequently does not occur because a bed of dense scar tissue is laid down as the foreign body burrows and advances. The rapidity with which stone formation occurs depends to a great extent on the physical characteristics of the foreign body and the degree of local irritation it produces.

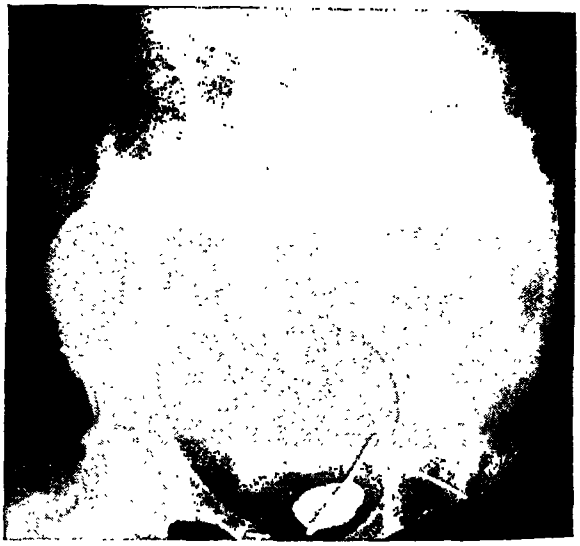

Fig. 2.—Preoperative roentgenogram showing bladder calculus, Steinmann pin, and fetal skeleton.

Summary

A Steinmann pin from a hip-pinning seven years previously migrated into the urinary bladder of a pregnant woman. The original orientation of the pin suggests that the pointed end first entered the bladder and that calcification of the distal end occurred only after the entire pin was intravesical, or nearly so.

The patient denied having had any operations in the past, and was therefore cross-examined regarding attempted abortion. The oral intake of liniment is not recommended as an effective abortifacient from this series of one.

SPECIAL ARTICLE

This is the first of three papers presented at the Midyear Conference of the American Hospital Association, Chicago, Feb. 4, 1959. The others will be published in THE JOURNAL, *June 13 and 20.*

THE JOINT A. M. A.–A. H. A. COMMITTEE ON PROFESSIONAL LIABILITY

Joseph F. Sadusk Jr., M.D., Oakland, Calif.

During the past decade, the problems of professional liability confronting both hospital and physician have become increasingly severe. Not only has the frequency of claims increased but also the amount of indemnities paid and judgments rendered. In some areas total losses now practically quadruple those of 10 or more years ago. This has resulted in an unprecedented rise in premiums for professional liability insurance, a manifestation of the increasing financial liability of the physician and hospital. Even more important is the indirect effect on the practice of the physician, not only inhibiting his use of the more serious and hazardous forms of medical and surgical treatment but also causing him to practice with one eye on his legal obligations. This is difficult since the practice of medicine generally still remains an art, rather than a business procedure or a purely scientific endeavor.

The problem reached such magnitude for the physician by 1954 that a number of resolutions were presented to the House of Delegates of the American Medical Association by its component state medical societies, requesting advice and assistance in the field of professional liability. In December, 1954, the Board of Trustees of the A. M. A. directed the Law Department of that organization to carefully review the problem and to plan and initiate appropriate studies on the subject. Such studies were made and progress reports were regularly presented to the Board of Trustees. These analyses covered state insurance laws and regulations, state statutes of limitations, the type of reported cases, professional liability claims involving physicians in government service and in civilian practice, surveys of pertinent state legislation, surveys of state and national medical societies, and, finally, the preparation and publication of special articles on the subject of professional liability.

These and studies elsewhere, especially in California, clearly indicated that the majority of claims against physicians arose in hospitals. The findings were striking, revealing that whether studies were made on a county, state, or national basis, 70% of such malpractice claims occurred in the hospital. This was interpreted as a manifestation of the fact that serious and difficult medical and surgical problems are carried out in the hospital rather than in the doctor's office or in the patient's home.

At the same time the California Hospital Association, by forming a group insurance program in the field of hospital liability, obtained invaluable data on factors leading to claims against the hospital. These findings, along with the findings of the Law Department of the A. M. A., led to a resolution adopted by the House of Delegates of the A. M. A. in June, 1957, directing the Board of Trustees to consider the advisability of entering into discussion with representatives of the American Hospital Association with the objective of formulating and implementing an effective joint in-hospital safety and accident prevention program. The A. M. A. Board of Trustees voted to approve the appointment of a joint committee shortly thereafter.

On Oct. 2, 1957, at the invitation of the American Medical Association, the Board of Trustees of the American Hospital Association took the necessary formal action to enable the appointment of a joint committee of the two associations on the subject of professional liability.

Six members were appointed to the Joint Committee, three each from the A. M. A. and the A. H. A. Dr. H. Close Hesseltine of Chicago, Dr. W. M. Nebeker of Salt Lake City, and Dr. Joseph F. Sadusk Jr. of Oakland, Calif., were assigned by the American Medical Association and Dr. Ray E. Brown of Chicago, Dr. August H. Groeschel of New York, and Mr. James E. Ludlam of Los Angeles were assigned by the American Hospital Association. The Joint Committee first met in session in Chicago on Oct. 17, 1957, assisted by Mr. Alanson W. Willcox, counsel for the American Hospital Association, and Mr. C. Joseph Stetler, Director of the Law Department of the American Medical Association. At that meeting, Dr. Sadusk was elected Chairman and Mr. Stetler was elected Secretary.

The directive for the Joint Committee was simple and broad in nature. The committee was asked to formulate and implement an effective in-hospital

---

Chairman, Joint American Medical Association–American Hospital Association Committee on Professional Liability.

safety and accident prevention program with a view to improving patient care, preventing accidental injury to patients, and lowering to an irreducible minimum grievances, claims, and suits against members of the medical staff and the hospital. Reports of the meetings of the Joint Committee have been received and accepted by the House of Delegates of the American Medical Association at its December, 1957, and June, 1958, meetings.

Joint professional liability problems of the physician and the hospital have been discussed in detail at meetings of the committee. Collection of facts and statistics dealing with professional liability and education in the field have been discussed on a local and national basis. A report concerning the history and present status of the legal liability of charitable hospitals, by state, has been submitted to the journals of the two associations for publication. A similar paper on legal liability of governmental hospitals has also been prepared.

Through one of the A. H. A. members of our committee, and with the guidance of the committee, the Farmers Insurance Exchange of California is conducting an intensive survey of the professional liability experience of 200 hospitals in California covered by the state hospital group insurance program. This study, which will cover the last four years, is intended as a pilot survey. It is hoped that the results and the system perfected will enable the committee to recommend a mechanism for similar analyses by other state groups and by individual hospitals.

Much discussion has taken place on the subject of education in professional liability for the physician and the hospital, particularly with the view of leading both the professional and the administrative staff to realize the joint nature of their problems. Careful consideration has been given to the formation of joint committees on professional liability at state and local levels. Also, discussion has brought out the need for methods of indoctrination and education at state and local levels, with educational material being prepared at the national level for guidance at the grass roots level.

Such is basically the purpose of this discussion today. As a primary source of educational material, the Joint Committee has planned, through the kind assistance of the Wm. S. Merrell Company of Cincinnati, a series of films on various aspects of the professional liability problem for hospital and physician. One such film, entitled "No Margin for Error," has already been completed and will receive its première showing today. This film takes up in-hospital liability problems and is directed not only to the physician's professional liability but also to the hospital and to its employees. The joint nature of such problems has been emphasized. This first film is necessarily general in scope; as time goes along, future films will doubtless be along more specific lines. The film may be obtained for showing in hospitals from the respective film libraries of the A. M. A. and the A. H. A.

The committee has considered that there is a need at the local hospital level for a joint hospital medicolegal education committee to provide all persons engaged in the care of patients with an understanding of the various factors which are or could be involved in the occurrence of accidental injury or harm to the patient. Details of this recommendation will be presented by Dr. Groeschel of the Joint Committee. Also, Mr. Ludlam will present our thoughts on similar committees at the state level.

Our deliberations to date have certainly emphasized the need for a joint effort of physician and hospital at all levels from national down to local. It is hoped that our committee's efforts will lead to the formulation of a sound prevention program which can be implemented by constituent associations and by individual hospitals.

4725 Telegraph Ave.

SURVIVAL AFTER HIP FRACTURE.—A comparison of the life expectancy of our patients following fracture with the life expectancy of a group . . . similar to our patients in age, sex, and race showed that after the first 6 months the life expectancy of our patients with fracture is not appreciably less than that of the general population, which is about 11 years. These conclusions would lead us to suggest that if patients with fracture of the hip can be supported through the first 6 months, they should live for several years. Although it is true that the weak members of the fracture sample would tend to die in the first 6 months, yet 70 per cent of our patients lived for 6 months. Every effort should be made to see that these patients are sustained to the maximum. We suggest that the use of heparin for the prophylaxis of pulmonary embolism, the liberal use of whole blood before and during operation (especially in the patients with trochanteric fractures), and the use of antibiotics for the prophylaxis of pulmonary and wound infections are helpful.—William T. Fitts Jr., M.D., Herndon B. Lehr, M.D., Stanley Schor, Ph.D., and Brooke Roberts, M.D., Life Expectancy After Fracture of the Hip, *Surgery Gynecology & Obstetrics,* January, 1959.

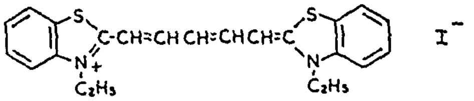
COUNCIL ON DRUGS

NEW AND NONOFFICIAL DRUGS

The following descriptions of drugs are based upon available evidence and do not in any case imply endorsement by the Council.

H. D. Kautz, M.D., *Secretary.*

Dithiazanine Iodide (Abminthic, Delvex).—3-Ethyl-2-[5-(3-ethyl-2-benzothiozolinylidene)-1,3-pentadienyl]benzothiazolium iodide.—The structural formula of dithiazanine iodide may be represented as follows:



Actions and Uses.—Dithiazanine iodide, introduced commercially in 1958, is a blue cyanine dye which is used clinically as an anthelmintic. The drug possesses an amidinium ion system, a distinctive chemical configuration characterized by a quaternary nitrogen separated from a tertiary nitrogen by a resonating or conjugated carbon chain of alternate double and single bonds; this resonating amidinium ion system is apparently essential for anthelmintic activity. Cyanine dyes as a class are sparingly soluble and poorly absorbed from the gastrointestinal tract. The high levels in the intestine after oral administration of dithiazanine exert an inhibitory effect on the anaerobic metabolic reactions of certain intestinal helminths, thereby producing a chemotherapeutic effect against susceptible parasites.

Dithiazanine is highly active against Trichuris trichiura (whipworms) and Strongyloides stercoralis. Cure rates ranging from 72 to 100% have been reported in trichuriasis and from 62 to 100% in strongyloidiasis. The drug is far more effective than previous modes of therapy in either of these worm infestations, i. e., hexylresorcinol retention enemas for Trichuris organisms and intravenously administered gentian violet for Strongyloides infections. In responsive patients, therapy with dithiazanine effects a cure rather than merely removing most of the worms. Hence, it is considered the drug of choice for the treatment of trichuriasis and strongyloidiasis.

Dithiazanine is about as effective as piperazine for the treatment of pinworms (Enterobius vermicularis) and roundworms (Ascaris lumbricoides). Since the use of dithiazanine is associated with a much higher incidence of gastrointestinal side-effects than is therapy with piperazine, the latter agent is considered preferable for these infestations. Therapy with dithiazanine for pinworms or roundworms should be reserved for those patients in whom a course of treatment with piperazine has failed to eradicate the parasites. However, dithiazanine should prove to be highly useful as a single agent for the treatment of multiple worm infections, such as ascariasis and trichuriasis, which frequently occur in the same patient.

Dithiazanine, used either alone or in combination with tetrachloroethylene, has been tried for the treatment of hookworm infections due to Necator americanus. Although the preliminary clinical trials have suggested some degree of chemotherapeutic effectiveness, the drug appears to be inferior to tetrachloroethylene for this purpose. Hence, its use in hookworm infections is considered experimental. There is, likewise, inadequate evidence to establish the usefulness of dithiazanine in dwarf tapeworm (Hymenolepis nana) parasitism.

Serious toxicity has not been encountered during the clinical trials of dithiazanine, an effect attributable to its almost complete lack of absorption from the gastrointestinal tract. The drug does, however, exert a local irritant effect on the gastrointestinal mucosa. Thus, nausea, vomiting, and anorexia occur frequently; abdominal cramps and diarrhea may also be encountered. For this reason, the drug is probably best administered with meals. Since cyanine dyes as a class are highly toxic when given parenterally, dithiazanine should not be given in any condition in which its gastrointestinal absorption might conceivably take place. In view of past experience that other cyanine dyes can cause kidney damage, dithiazanine should be used cautiously in patients with renal disease. The drug is obviously contraindicated in any condition that may be aggravated by vomiting.

Dosage.—Dithiazanine iodide is administered orally. The optimal daily dose is 45 mg. per kilogram of body weight (20 mg. per pound) with a maximum daily dosage of 600 mg., administered in three divided doses, for 5 to 10 days in trichuriasis, for 5 days in ascariasis and enterobiasis, and for 7 to 21 days in strongyloidiasis.

Preparations: tablets 50, 100, and 200 mg.

Eli Lilly and Company cooperated by furnishing scientific data to aid in the evaluation of dithiazanine iodide.

COMMITTEE ON TOXICOLOGY

Accidental poisoning from a compound or group of compounds is directly related to accessibility of the agent and lack of awareness of its toxic potentialities. This is no more strikingly demonstrated than in the record of poisoning from medicinal iron preparations during the past century. Over 100 years ago, Orfila, the father of the modern science of toxicology, pleaded for recognition of the toxicity of ferrous sulfate because of the then increasing number of poisonings by iron salts. Later, the medicinal value of iron preparations fell into disrepute, and iron poisoning vanished with the disappearance of these preparations from the home.

Orally administered iron preparations have again returned to medical favor, but a general lack of awareness of the hazard of overdoses, especially in small children, persists. Accordingly, the Committee has adopted the following report to acquaint the medical profession and, through them, the general public, with the toxicity of iron salts and their potentialities for harm when ingested in excessive amounts.

Bernard E. Conley, Ph.D., *Secretary.*

ACCIDENTAL IRON POISONING IN CHILDREN

Within the last 10 years a considerable number of small children have been poisoned from the accidental ingestion of ferrous sulfate tablets. The potential toxicity of ferrous sulfate has received editorial attention in recent years, and physicians have been asked to adopt a more cautious attitude about the supposed safety of iron preparations. In view of the accumulated reports of poisoning by ferrous sulfate and other iron salts such as ferrous and ferric chloride and ferric ammonium citrate and the current popularity of this form of therapy, it is important that physicians appreciate the potential toxicity of these compounds and warn patients to keep tablets out of the reach of children.

The incidence of poisoning by iron salts seems to be related to the status of iron therapy in any given period. Cases of accidental and homicidal poisoning from iron salts were widely reported in the literature of the middle 19th century. Reports of accidental iron intoxication did not appear again in print until 1934, and since 1947 they have appeared with sufficient frequency to warrant editorial attention.

Until the last decade of the 19th century, iron therapy was widely employed in the treatment of hypochromic anemias due to body-iron deficiencies. At the turn of the century a definite change in attitudes toward the value of iron therapy occurred as the result of the belief that inorganic iron was not absorbed from the gastrointestinal tract. The small doses of iron salts then used had little therapeutic effect, and the value of iron fell into disrepute until the second decade of this century. Then, the two fundamental principles of iron therapy previously set forth by Sydenham and Blaud, namely, large doses and the greater potency of ferrous salts, began to be reconfirmed through use.

In recent years, ferrous sulfate has been used extensively for the treatment of iron deficiency anemia, and even some blood banks give the tablets routinely to donors. The more widespread use of this compound has increased the opportunity for accidental poisoning in young children. Candy-coating of this medication appeals to small children, thereby magnifying the hazard. The magnitude of the hazard is evident in the vital statistics on fatal accidental iron poisoning which have been recorded in the United States and Great Britain in recent years.

Clinical Experience

In Great Britain, ferrous sulfate is considered the most important childhood poison, being comparable to aspirin in the United States as the greatest single cause of poisoning in small children. Two decades ago (1930-1939) only two children died in Great Britain from ferrous sulfate poisoning. During the recent decade (1940-1949) this drug killed 17 children, with two more deaths attributed to unspecified iron tablets. Although full information is not available for recent years, the direction of the trend of iron poisoning is evident from British vital statistics for 1950-1953. These records indicate that 32 accidental deaths due to ferrous sulfate poisoning occurred in children.

Although precise data for a comparable period for the United States are not available, eight deaths are recorded in the American literature for the period 1947-1954. Examination of mortality data recorded with the United States' National Office of Vital Statistics disclosed 30 deaths from ferrous sulfate in children for the years 1949 through 1956.

Unfortunately, nationwide morbidity data are unavailable. Examination of the records of the New York City Poison Control Center revealed that ferrous sulfate was involved in 35 incidences reported during the past two and one-half years. The Washington, D. C., chapter of the American Red Cross tabulated only six nonfatal reports during the same period. An additional 68 cases were reported from 16 other centers responding to a questionnaire directed to poison control activities. These data suggest that, although poisoning from oral ingestion of medicinal iron preparations is not as important a cause of injury in the United States as in Great Britain, prudent use of such preparations requires that warning or caution statements about the hazards to children be required of all oral iron preparations with a history of accidental injury. For several years, British manufacturers have employed warnings of this type on the labels of containers for iron sulfate capsules and tablets. Canadian food and drug regulations also require caution statements on ferrous sulfate capsules or tablets.

Mechanism of Action

The mechanism of action in iron poisoning is not known. Pathological findings have failed to give a satisfactory explanation for death. Opinions are divided as to whether the fatal outcome is due to shock secondary to local tissue damage to the gastrointestinal tract, to systemic effects following the passage of large quantities of iron into the blood stream, or to the metabolic effects of absorbed iron resulting in respiratory collapse.

One of the unique features of iron metabolism is that iron has no organ of excretion. Iron released from the catabolism of iron compounds is not excreted and must be fed back into anabolic iron pathways. Overloading with parenterally administered iron is not compensated for by increased fecal or urinary excretion. Iron found in the feces represents only unabsorbed iron, and the intestine has no power to regulate, through excretion, the amount of iron in the body. Urinary excretion of iron is negligible, and increased ingestion of iron is not accompanied by elevated urinary excretion. Thus, the capacity to regulate the amount of iron in the body lies in the absorption mechanism.

Iron is absorbed by the mucosal cells of the intestinal tract. It is absorbed more readily in the ferrous than in the ferric form. How iron passes through the mucosal cell and into the blood stream is unknown. The absorption of iron is not a question of simple diffusion across a membrane but involves a metabolic transportation through the intestinal mucosa. Presumably, the mucosal cell regulates the rate of absorption from the gastrointestinal tract and seems to act as a barrier to the rapid entrance of iron into the circulation.

The pathological picture is usually that of hemorrhage and necrosis of the stomach and intestinal mucosa. The liver is frequently involved, showing mild, cloudy swelling to small areas of complete necrosis. Among some survivors, delicate fibrosis of the liver and pyloric stenosis have been described. In most cases there has been a marked dilation of the right side of the heart, with pulmonary congestion and occasional hemorrhage. There have not been any particular abnormal findings in other organs of the body.

Symptoms and Treatment

There are three critical phases in iron poisoning: an early acute phase of shock that occurs within a few hours after ingestion; a recurrent phase that appears 20 to 48 hours after ingestion; and occasionally a late phase of gastric scarring and contracture, with pyloric obstruction appearing about a month later.

Death has occurred from the ingestion of ferrous sulfate in doses ranging from 40 to 1,600 mg. per kilogram of body weight. Hoppe has estimated the fatal dose for a child 2 years old or younger to be 900 mg. per kilogram of body weight.

The principal manifestations of poisoning are vomiting and circulatory collapse. Lethargy, vomiting, fast and weak pulse, low blood pressure, and coma appear within one-half to one hour after ingestion. These symptoms may disappear after 4 to 6 hours, followed by a 6-to-24-hour asymptomatic period in which the child seems to improve rapidly. A second crisis then occurs, with cyanosis, vasomotor collapse, pulmonary edema, coma, and death within 12 to 48 hours.

Treatment is mainly symptomatic and is directed toward removing the iron and combating shock. Milk should be given immediately and vomiting induced. The stomach should be lavaged with a 5% aqueous solution of monosodium phosphate or disodium phosphate. Two or three ounces of the phosphate solution should be left in the stomach of a child 1 or 2 years old. (Proportionately greater amounts of these drugs may be given to older patients.) Bismuth subcarbonate, 200 mg., may be given every four hours to young children. A solution of 5% glucose in saline solution should be administered intravenously to correct dehydration. Transfusion is initiated with plasma or whole blood if shock is severe. Edathamil calcium-disodium is administered intravenously, and oxygen is given as indicated. Exchange transfusions have proved valuable in severe poisoning. Antibiotics are administered as prophylaxis against pneumonia and other intercurrent infections.

Conclusions

The approach often recommended to correct most poisoning hazards is to substitute less noxious agents or to restrict use so that the hazards are reduced or eliminated. Iron sulfate and other iron salts, which have produced injury, may ultimately be replaced by safer iron compounds, provided the substitutes are equally effective and not too expensive. Restrictions on use, although theoretically attractive, are not always feasible in practice, especially for a valued and time-tested medicinal agent. A requirement that ferrous sulfate and similar hazardous iron salts be labeled with a caution statement about the hazards of excessive doses, especially to children, seems to best serve the public interest at this time.

IS FAMILIAL PERIODIC DISEASE A NOSOLOGICAL ENTITY?

A case report in this issue of THE JOURNAL, page 653, by Alkalay and co-workers calls attention to a syndrome that seems to be in the process of being differentiated from the pyrexias of unknown origin. In 1948 Reimann [1] grouped together under the term periodic disease a series of patients with somewhat diverse symptomatology, characterized by periodic recurrence of symptoms over a long period of time and without known cause. The findings most frequently noted were recurring fever, abdominal pain, and joint pain. Similar cases have been described by others under such terms as benign paroxysmal peritonitis, periodic peritonitis, periodic arthralgia, periodic abdominalgia, and familial Mediterranean fever. Heller and associates [2] proposed the following diagnostic criteria: (1) attacks of fever, usually of short duration, recurring at varying intervals over the course of many years; (2) painful manifestations usually but not always with each attack located in abdomen, chest, joints, or skin; and (3) no evidence of any known causative factor. About one-third of the patients develop erythematous skin lesions and about one-fourth develop proteinuria without obvious cause.

Similar symptoms have been found among close relatives of about 60% of the patients described in the literature. Reimann and Angelides [3] described 23 affected persons in five generations of a single family, with arthralgia being the outstanding symptom. Genetic study of this family and of several others suggests the action of an autosomal dominant gene. On the other hand, Mamou and Cattan [4] described 10 cases in first cousins and their children, but with two normal sisters who were mothers of the affected sibships. This observation, which has been supported by others, suggests that the condition can be transmitted to their children by apparently healthy persons. This phenomenon, which would be described by geneticists as reduced penetrance of the gene, at least suggests the possibility that both genetic and environmental factors might be concerned in the etiology of this condition. In addition, familial periodic disease seems to have a peculiar ethnic distribution, occurring primarily in peoples of the Mediterranean Basin, and in their descendants in other parts of the world. The vast majority of cases have been found in Jews, Armenians, and Arabs, with some cases in Turks and Italians.

The picture that seems to be evolving is that of an inherited disease of unknown mechanism and apparently limited ethnic distribution that should be considered in the differential diagnosis of fevers of unknown origin. The frequent occurrence of renal involvement suggests that this condition may also be responsible for some of the obscure cases of nephritis. Additional studies with a combined genetic and clinical approach are needed to delineate this syndrome more exactly and to elucidate the mechanisms involved in its development.

NUCLEAR SEX

In 1949, Barr and Bertram [1] demonstrated a sex difference in nuclear morphology in the neurones of the cat. Subsequently similar though possibly not homologous distinctions were shown to exist in cells of many other tissues in a variety of species including man. In recent years, the sex chromatin test has been widely used in studies on sexual dysgenesis and neoplastic growths and has provided a useful tool in the field of experimental embryology. Various cell preparations have been used for the test including buccal and vaginal smears, amniotic fluid smears, skin biopsy specimens, and leukocytes. In somatic cells other than leukocytes a characteristic chromatin mass is found on or close to the nuclear membrane in from 25 to 85% of cells from genetically female persons but in less than 10% of cells from genetically male persons. This mass may represent the two X chromosomes of the female, though this is by no means established nor is there any explanation for the occasional appearance of this structure in male cells.[2] The sex distinction in the leukocyte is manifested by a small drumsticklike structure present in up to 6% of leukocytes of genetically female persons but absent from leukocytes of genetically male persons.[3] The significance of this structure has not been determined. With the possible exception of certain neoplastic growths,[4] there appears to be a consistent agreement in chromatin sex among the various tissues of a given person; the pattern is apparently established early in the embryonic development, persists through the life of the person, and is uninfluenced by hormone administration or deprivation.

It is now well established that the influence of genetic, environmental, or hormonal factors during development can lead to a dichotomy between genetic and somatic sex. Thus dysgenesis of the primordial germ cells may apparently lead to either Turner's syndrome or Klinefelter's syndrome depending, respectively, on whether the germ cells disappear completely or are merely substantially reduced.[5] In the former case, the phenotype is invariably female though the genetic sex has been found to be male in the majority of subjects examined. In the latter case, the medullary component of the fetal gonad is able to differentiate and a testis results, capable of secreting testosterone and even of displaying spermatogenesis. Male secondary sex characteristics develop regardless of the fact that the genetic sex has proved to be female in many of the clinically recognized cases. In the event that the number of primordial germ cells approaches the normal, true hermaphroditism may result, the persons being of either male or female genetic sex. While it is generally agreed that these forms of sexual dysgenesis must arise very early during development, opinions differ as to whether they are genetically determined disorders[6] or acquired ones.[5] Another abnormality, the testicular feminizing syndrome, is known to be the result of a maternal hereditary trait which manifests itself early in the third month of pregnancy by suppression of the male inductive and endocrine capacities of the testes. Genetically male offspring of mothers bearing this trait develop female or mixed male and female secondary sex characteristics. Female offspring develop normally but one-half will be carriers of the trait.

A third type of defect, congenital adrenal hyperplasia, arises from a genetic defect in the synthesis of adrenal cortical hormones which leads to an enhanced production of androgenic substances. This results in various degrees of virilization particularly apparent in female babies. Fortunately this condition usually responds readily to depression of endogenous adrenocorticotropic hormone secretion by corticosteroid therapy. A somewhat similar form of female pseudohermaphroditism has been reported to occasionally occur in female children born to women receiving progesterone during pregnancy.[7] In these cases, it has been suggested either that the placental barrier is abnormally permeable or that the mothers degrade progesterone abnormally, giving rise to more potent androgenic substances. Determination of the genetic sex is of considerable aid in the diagnosis of those essentially treatable forms of pseudohermaphroditism.

In lower vertebrates, sex reversal has been shown to be compatible with reproduction. Thus, the genetically male Xenopus can be changed to a normally behaving, reproducing female frog.[8] As yet complete sex reversal has not been recorded in man, though the presence of active spermatogenesis in certain genetically female patients with Klinefelter's syndrome suggests this possibility. Recognition in man would be difficult since sex reversal usually only comes to the attention of physicians when patients seek medical advice for such conditions as sterility. Recently Moore[9] has reported that in 1,911 newborn anatomically male infants, 5 had sex chromatin patterns typical of females while in all of 1,804 anatomically female infants the chromosomal pattern was characteristically female. An even higher incidence of sex reversal has been reported by Ferguson-Smith[10] in prepuberal mentally retarded children. Moore suggests that if all five of the chromatin-positive males develop testicular dysfunction before puberty, the incidence of the disorder must be higher than is generally thought. Alternately he postulates that at least some of the five may develop into normal-appearing, fertile males. Recognition of such sex-reversed persons is currently being attempted by cytological screening of fathers of families composed of large numbers of girls only, since genetically female persons mated to normal females could be expected to have only female offspring.[11] The possibility of the existence of fertile sex-reversed persons serves to stress the fact that the ultimate determination of sex should not be based on chromatin patterns alone but on a consideration of the total psychophysical personality.[12]

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

In this final message of mine to the 175,000 members of the American Medical Association I am extremely pleased to report to you that I believe the state medical societies are meeting one of medicine's most important challenges—the health care needs of the aged—with speed, vigor, and imagination.

In the last few months I have had the opportunity to see firsthand how our state medical associations are moving to solve this important matter now before the profession. I have heard the discussions and debate of state committees on aging and of houses of delegates. I have watched hundreds—even thousands—of physicians toiling over and thinking out new and better medical care plans for their fellow men—the senior citizens of the United States.

Since the A. M. A. House of Delegates unanimously adopted the proposal asking physicians to accept a level of compensation that would permit the development of low-cost health insurance and prepayment plans, our state associations and their members have seized the opportunity before them and have implemented this decision.

In full cooperation with Blue Shield plans across the nation low-cost coverage for older persons has been developed in many areas. Some of these plans now are enrolling those over 65 years of age. Others soon will begin their enrollments.

In a realistic fashion these states have come up with plans that will provide tangible help and needed security and assurance to our aged. They have done so not merely because of the essential urgency of the situation but, more important, because here was an opportunity for the physician and his organized medical society to serve patients—millions of them over 65 years of age.

Without a doubt, this dedicated action on the part of physicians everywhere has been the highlight of my term of office. It has been a most heartening experience. Furthermore, I believe that every physician who has taken part in this excellent effort to develop a sound and workable plan in his state has been rewarded richly.

I cannot thank personally every physician who has taken part, or who will participate, in this program of helping the aged to help themselves in meeting their health care needs. However, through this medium I congratulate each of you for your past, present, and future good work.

Naturally, I am aware that what we already have done does not necessarily make medicine's program for the aged a success. Our ultimate and real success will be measured in the number of older persons who are covered by voluntary health insurance and prepayment plans and the extent of that coverage.

But a solid foundation has been laid. We now need to build on it. Furthermore, we need to keep the profession mobilized and alert on the whole matter of the aging.

I also hope that all our state societies will display their further interest by enlisting community support and by providing leadership in obtaining adequate nursing home and homemaker facilities for the aged at the community level.

In his famous passage from "Rabbi Ben Ezra" the poet Robert Browning wrote:

"Grow old along with me! The best is yet to be."

For the sake of all of the nation's aged and of future generations of senior citizens, I hope that we—the physicians of the United States—will continue to do our utmost to ensure that truly "the best is yet to be."

Gunnar Gundersen, M.D.
La Crosse, Wis.

ORGANIZATION SECTION

REPORTS OF OFFICERS

The following reports will be presented to the House of Delegates of the American Medical Association at its session to be held in Atlantic City in June.

REPORT OF BOARD OF TRUSTEES

To the Members of the House of Delegates of the American Medical Association:

The following report of the Board of Trustees is respectfully submitted:

Financial Statement

The official 1958 financial reports of the Association's accountants appear as part of this report.

At its meeing on April 24-26, 1959, the Board of Trustees adopted, on recommendation of the Association's accountants, a form of balance sheet which constitutes a revision, particularly with respect to reserves and fund balance, and which was made applicable to the accounts as of Jan. 1, 1959. The letter from the accountants, transmitting the revised balance sheet, indicated that "as further funds are set aside and reserved, entries should be made in the accounts and so shown in the financial statements that the resources of the Association which have been authorized to be set aside by the Executive Committee are clearly indicated. We approve of the revised form of presentation and it is our understanding that this will become the official form of balance sheet presentation for American Medical Association, effective January 1, 1959."

The above revised balance sheet also appears as part of this report.

Report on Matters Referred by House of Delegates

Voluntary Health Agencies.—In December, 1958, the House of Delegates adopted a substitute resolution stating that the American Medical Association neither approves nor disapproves of the inclusion of voluntary health agencies in united fund drives and that the Board be requested to arrange a top-level conference with the voluntary health agencies, the united funds, and other parties interested in the raising of funds for health causes, with the view of resolving these misinterpretations and other difficulties in this area.

After careful consideration of the resolution and the intent of the House which was interested as a desire to clarify the position of the American Medical Association with respect to fund raising, the Board of Trustees was of the opinion that such clarification could be accomplished by sending a letter to the organizations concerned. The letter, outlining the December 1958 action of the House of Delegates, was mailed in March 1959.

Armed Forces Institute of Pathology.—In accordance with the action of the House of Delegates in December, 1958, a letter was sent to the Secretary of Defense requesting that provision be made for general or flag rank for the Director of the Armed Forces Institute of Pathology during his tenure of office.

A reply from Charles C. Finucane, Assistant Secretary of Defense, Manpower, Personnel and Reserve, dated March 26, 1959, indicated that the views of the Military Departments on the resolution were obtained; that the Departments, while expressing full recognition of the importance of the position and the necessity for capable service representatives occupying it, are unanimous in the opinion that the position should not be designated for general/flag officer rank. The reasons cited are (1) that the specialist qualifications which the Director must possess preclude the routine assignment of a general/flag officer to the position; (2) the Services are unable to accommodate within present general/flag officer authorizations a number of positions for which the assignment of a general/flag officer is considered fully justified. Their capability to meet requirements for general/flag officers outside their own areas is limited to filling only those positions related to the highest priority missions. Accordingly, it is the view of the Department of Defense that the establishment of the position of the Director of the Armed Forces Institute of Pathology for general/flag rank is not desirable.

Memorial Stamp Commemorating Anniversary of First Successful Oophorectomy.—A telegram was sent to the Postmaster General requesting, in accordance with the action of the House of Delegates in Minneapolis, that a commemorative stamp be issued in honor of Dr. Ephraim McDowell who performed the first successful oophorectomy on Dec. 25, 1809, at Danville, Ky. Mr. L. Rohe Walter, Special Assistant to the Postmaster General, replied that a number of requests for such a stamp were received and given complete and careful consideration by the Citizens' Stamp Advisory Committee; that while the Committee appreciates the significance of the great contribution made by Dr. McDowell, it was not possible to include recommendation for this stamp in the 1959 schedule.

Referrals.—Other matters referred by the House of Delegates to appropriate councils, committees or departments of the Association have been so referred. As soon as reports are available from these groups, they will be transmitted to the House of Delegates.

Committee on Preparation for General Practice

In June, 1958, the Board of Trustees referred to the House of Delegates for its information a progress report of the Committee on Preparation for General Practice, for the purpose of obtaining comments and suggestions from the members of the House in order to aid the Committee in developing a final report at a later date.

The following final report and recommendations of the Committee on Preparation for General Practice was approved by the Board of Trustees and is submitted to the House of Delegates for adoption:

Introduction.—At the meeting of the House of Delegates of the American Medical Association in Seattle, Nov. 27-30, 1956, the Committee on Medical Practice presented a report containing five instructions. The report was considered by the Reference Committee on Insurance and Medical Service and on its recommendation was adopted by the House. The report, in its instructions 3 and 4, recommended that a study group be formed to consider the best background preparation for general practice.

The Executive Committee of the Board of Trustees, at its meeting on Dec. 14, 1956, voted that the Council on Medical Education and Hospitals address itself to instructions 3 and 4 and requested the Council to form a study group of representatives of the Council, the Association of American Medical Colleges, the American Academy of

General Practice, and representatives of the specialty areas, and proceed "to analyze objectively and make recommendations as to the best background preparation today for general practice."

Subsequently, the Committee received a related assignment from the House of Delegates during the New York meeting, June 3-7, 1957. At the time that the Reference Committee on Medical Education and Hospitals considered the reports of the Klump Committee on General Practice Prior to Specialization, it recommended discharge of that Committee and also "that the newly organized committee to study the best background preparation for general practice, in its long-term cooperative study with appropriate groups, give full consideration to the importance of a broad background of training and experience for all physicians in the care of the patient as a whole and of the family as a unit."

The first meeting of the Committee on Preparation for General Practice occurred Jan. 18, 1957. There have been subsequent meetings, as follows: Subcommittees—May 9, June 28-29, and Oct. 20, 1957. Committee meetings—May 10, Sept. 14 and Dec. 5, 1957; Feb. 22-23, May 17, and Sept. 13, 1958, and March 20-21, 1959. Discussions have been held with various major specialty groups in order to secure the benefit of their thinking in the deliberations of the Committee.

General Considerations.—The Committee undertook its assignment in full recognition of the need for a long range objective study regarding what basic educational background would best prepare future physicians for general practice. This immediately raised questions about the future nature of such practice in the light of the needs of the people as well as the changing dimensions of medical knowledge.

After careful thought and study of pertinent data, the Committee has concluded that the marked trend toward what is called full time specialty practice will be of continuing significance. As knowledge important to medicine continues to increase, the further development of specialism and its related tools and techniques will also take place. Although the availability of such specialty service is essential to good medical care, it is believed that it is similarly important that the broad, general outlook in medicine also be retained.

The Committee is of the opinion that the needs of the public are well served through comprehensive medical care. By its very nature, such care is based necessarily upon a close interpersonal relationship that most readily develops through long association between a physician and a patient. To have greatest significance, this close relationship also involves the physician with his patient's environment and, most particularly, with his family.

There is a general awareness of the changing nature of society. It is proper and necessary that the pattern of medical care adapt itself to fulfill best its role in this changing order. An unknown degree of such adaptation, not measurable in available data, has already taken place.

It is recognized that the approach to medical practice with the humanistic concept of and concern for the "whole patient" is and indeed should be characteristic of all physicians whether specialists or not. However, the concept of comprehensive medical care, as used here, implies the active performance of direct service over broad areas of medicine and the availability of this broad service for all patients. The Committee believes that further changes in the pattern of medical practice and of graduate study for practice will be required to meet successfully the challenges of this kind of general medical care in the future.

It does not seem likely that the general practitioner, the internist, or other specialist as commonly conceived today will be ideally prepared to fulfill this role in the future. To do so, the general practitioner of the future should have a deeper and more extensive graduate medical education than is presently available. And if the internist were to assume this role, then his training should be broadened in preparation for the assumption of a more comprehensive and continuing responsibility for the health of the individual and his family regardless of age. Thus, there are two possible approaches to the basic preparation of physicians for family practice; namely the designing of a new high quality graduate program specifically for the preparation of family physicians, or the broadening of the training given in existing residencies in internal medicine, such as by inclusion of training in pediatrics, the primary management of trauma, etc. The proposed program here set forth is concerned with the former. It is the hope of the Committee that appropriate groups will give consideration to the latter. It may well be to the advantage of the medical profession and the public that both approaches be used simultaneously.

In considering preparation for this type of medical practice in the future, the Committee devoted much thought to the titles that should be used for such a physician and such a medical practice. Because the emphasis is on the medical care of the family regardless of age and because of the wide acceptance and stature of the titles with the public, such a physician could most appropriately be designated a family physician and the field as family practice.

For the working definition of the medical practice involved, the Committee adopted the following: "Family practice is that aspect of medical care performed by the Doctor of Medicine who assumes comprehensive and continuing responsibility for the patient and his family regardless of age."

The educational program proposed for future family physicians is intended to prepare them to provide services to patients irrespective of age over broad areas of medicine and to coordinate specialty consultation and care according to the peculiar needs which their patients' problems may require. The Committee believes that there will be an increasing need for the family physician who is prepared to provide these services.

The Committee has given attention to the trend toward group practice. This trend, in itself, serves to emphasize the need for physicians prepared to serve as family physicians and for their inclusion in such groups.

The Committee believes it to be in the best interests of medical practice, the public, and the profession itself that every physician should be free to follow that field of medicine which most appeals to him and for which he is most suited by ability and temperament. He should be trained adequately for that field which he elects to follow. The student contemplating his future career in family practice should have avaiable to him recognized educational programs of high quality comparable to those existing in specialty areas.

Before addressing itself to the new graduate program, the Committee wishes to express certain viewpoints in regard to the medical school experience that is a necessary prelude to any graduate program. Regardless of what his future career may be, and this is not usually determined with finality early in his studies, the physician must have a sound balanced education in the sciences basic to medicine and in their clinical application. There is a common fund of knowledge and skills desirable for all graduates of medical schools. The provision of this common fund of knowledge and skills is the major objective of medical schools.

The educational program in a modern medical school exposes the student to specialty viewpoints. To maintain the objective of providing a sound, balanced medical education, it would seem highly desirable that the student be exposed also to the concept of family practice. Because general care is an important part of medical practice, medical schools should be encouraged to develop that phase of medical education centered around the patient, his continuing care, his environment, and the use of community resources, to the fullest extent compatible with the total educational program. Educational experiences emphasizing care of ambulatory patients should be an integral part of this program.

The Committee is cognizant of the many studies being conducted for the improvement of the medical school curriculum, and of the several experimental approaches being applied. These efforts are commended. The Committee believes that the entire medical curriculum warrants constant reappraisal and study for the purpose of developing educational programs which will better prepare the graduate to gain maximum advantage from the greater clinical opportunities of his graduate training. The medical profession has been fortunate in having medical school faculties who have subjected the educational objectives, methods and content to a continuing, intelligent, and critical appraisal. Careful, intensive study has frequently led to well planned changes. The Committee believes that the means of accomplishing further changes in undergraduate medical education should be left to the administrators and faculties of the schools, in whose ability and integrity the Committee has confidence.

The remarkable advances in medicine that have occurred and that will continue to occur have increased the difficulty and the complexity of family practice, as well as of the limited specialties. The responsibility of the family physician is a heavy one. It demands knowledge, alertness, agility of mind, and a wisdom born of education and experience. It necessitates the possession of a sound knowledge of the fundamentals of medicine as well as a synoptic knowledge of the basic principles of special fields. In view of this, as well as the pattern that has been followed successfully in the specialty fields of developing graduate educational programs beyond medical school, the Committee recommends that a new graduate educational program for family practice be developed.

The Proposed Basic Program.—The proposed two-year program presented below should assure the opportunity for adequate preparation of the future physician to provide medical care for all members of the family. It should be emphasized that the proposed program is conceived in its entirety as concerned with the preparation of physicians in the future for family practice. It should not be interpreted by hospitals or other institutions or organizations as having import for the training or privileges of general practitioners now in practice.

In recommending a new graduate program for the family practice of medicine, the Committee believes that primary consideration should be given to an educational experience enabling the physician to provide medical care for all members of the family irrespective of age. After determining that the period beginning at the time of receiving the M.D. degree is the most appropriate one for a new plan of preparation for family practice, the Committee agreed to concern itself with a minimal or basic program. Since the program is designed to fulfill a logical need, it is reasonable to anticipate that state board regulations, military obligations, and hospital staff policies and privileges will be altered to recognize the merits of this program.

Relationship to the Existing Internship.—The internship year as presently constituted cannot be considered as a component of this program for it would result in dividing it into two separate segments. The internship was designed many years ago to provide the initial contact with and responsibility for patients. Since the development of the medical school clinical clerkship, the internship no longer comprises such initial patient contact but rather it is now considered as one of several graded steps toward the assumption of total responsibility for patient care. Further, there is now general agreement that the one-year internship alone is inadequate as preparation for the practice of medicine. Indeed, the Committee believes the one-year internship actually encourages inadequate preparation for family practice.

The present values of the internship will be an inherent part of the proposed program, but cannot be separated out of it as a segment without weakening the greater values to be derived from dealing with the new program as a unified whole. The graduate program proposed as preparation for family practice is designed to be more comprehensive than the internship in regard to patient responsibility, educational content, and continuity of experience.

Minimal Requirements of the Basic Program.—Under the existing circumstances, the Committee believes that a period of at least two years of formal hospital training following attainment of the medical degree is necessary in preparation for the family practice of medicine. However, time alone cannot serve as a valid measure of educational adequacy. The two-year period would be minimal even where the other factors of educational quality and content are optimal.

Medicine and Pediatrics.—Since in usual instances the participant will enter this program immediately following graduation from medical school, it should include a minimum basic eighteen month period to provide experience in the diagnostic, therapeutic, psychiatric, preventive, and rehabilitative aspects of medicine and pediatrics in a very broad sense, including care of the newborn. In addition, there will be provided an elective period.

The graduate program of two years in preparation for family practice should be planned and implemented as a unified whole. Since the family physician is to provide continuing care, it is highly important that the preparation for this kind of practice be designed to assure suitable opportunity for the participant to study patients over relatively long periods of time. He should follow the patient, as necessary, in the outpatient service, into the home when this is practicable, and certainly from one hospital service to another (such as following his assigned patients from the medical or pediatric service through the surgical wards). There should be a maximum continuity of assignment in specific services so that the program will stress education through continuing rather than episodic medical experience. Such a unified two-year program will permit and encourage the necessary progression of responsibility.

Obstetrics and Gynecology.—The opportunity for training in obstetrics during the elective period should be a requisite of all programs. Participants who plan to practice obstetrics are expected to spend at least four months in obstetrical training. Physicians planning to undertake other than uncomplicated procedures should take additional advanced training in this field. For those who do not anticipate an obstetrical practice, the elective portion may be utilized for further training in other segments of the program. Experience should be provided in office-type gynecology (and the care of the newborn if not included in pediatrics). It is urged that the concept of unity be applied to the elective period to prevent unduly short assignments that would provide little educational justification.

Ambulatory and Outpatient Care.—Because the care of the ambulatory patient is an important part of medical practice, provision of adequate opportunities for the study of outpatients is essential and should be provided throughout the program insofar as practical in a manner that would permit following the patient over long periods of time.

Particularly with regard to the admission of ambulatory patients, it would be desirable if opportunity were provided in this program for their initial work-up before they are labelled as medical or surgical, in order that conditions ultimately treated surgically can be a part of the diagnostic experience of this program. This study of patients before identification of their illnesses as "medical" or "surgical" may begin in the outpatient department. It may continue in the hospital on the general medical service, but some hospitals may find it more convenient to establish admitting services for this purpose. Such training in diagnosis is essential if the conditions of a family practice are to be simulated.

Emergency Service and Surgery.—Throughout the two-year program, the participant should have experience provided by regularly assigned periods of emergency room service. The Committee believes that this should include training in minor surgery and the emergency and primary management of trauma. The emergency room service should also provide experience with the common medical and surgical emergencies and participation in their management. Participants in this program planning to undertake surgery other than minor surgery are expected to take additional advanced training.

Conclusions.—This report presents the minimal program under optimal circumstances for preparation for family practice in the future. The Committee believes that this two-year program would furnish a sound foundation for further graduate medical education and for continuing education in any field. The thoughtful cooperation of specialty groups will be essential to its success.

The Committee also recognizes that thoroughly sound implementation of the proposed program by medical staffs and governing boards of suitable hospitals will be required in order to realize fully its potentialities. The proposed program should receive the favorable attention of the best medical centers in this country. To achieve the ultimate objective of sound preparation in the future for family practice, this program should be initiated in suitable hospitals with the emphasis on quality.

Recommendations.—The Committee on Preparation for General Practice recommends to the Board of Trustees that (1) this report and specifically the basic program designed for preparation of family physicians be approved in principle and transmitted to the House of Delegates with a recommendation for its approval, (2) the Council on Medical Education and Hospitals be instructed to implement the intent of this report. Due attention should be given to the importance of initiating this new program on a modest scale so as to best assure that a high quality of educational experience will be a uniform characteristic of all such programs established. The Council on Medical Education and Hospitals should regularly and carefully review established programs so that Essentials of Graduate Training for Family Practice can be documented on the basis of sound experience.

With the submission of this report, the Committee has completed its assignment and requests that it be discharged.

Youth Fitness

The American Medical Association has had a long-standing interest in the fitness of youth, and, through its Department of Health Education and other departments and divisions, its Joint Committee with the National Education Association and many other cooperative relationships, has devoted considerable energy and effort to the improvement of youth fitness through a broad program of health education designed to emphasize intellectual, emotional, social, and moral and spiritual, as well as physical components of fitness.

The President of the United States has activated a Council on Youth Fitness among his Cabinet Members and has appointed a Citizens Advisory Committee on the Fitness of American Youth, composed of representative American leaders including several physicians, which are developing plans, suggesting projects, and recommending practices that are generally in keeping with the broad point of view on youth fitness held by the medical profession.

The views of the President's Council and the President's Citizens Advisory Committee on the Fitness of American Youth have been expressed as: to encourage the expansion of health education, to increase the status of physical education, to encourage continuing health supervision including periodic medical examinations and follow-up.

The Council and the Advisory Committee, in their deliberations, have emphasized the importance of developing youth fitness programs through existing agencies and organizations to prevent unnecessary duplication of services and facilities and cumbersome bureaucratic structures.

The Board of Trustees recommends that the American Medical Association, through the House of Delegates, approve in principle the aims and objectives of the President's Council and the President's Citizens Advisory Committee on the Fitness of American Youth and urge its member physicians to cooperate in the promotion of properly developed and soundly conceived plans and programs for youth fitness.

It also recommends that the constituent associations and their member local medical societies be requested, through their designated representatives, to work cooperatively with reputable professional and other ethical groups interested in the improvement of youth fitness.

Copies of this statement, if approved, should be transmitted to the President of the United States, to the members of the President's Council on Youth Fitness, and to the members of the President's Citizens Advisory Committee on the Fitness of American Youth.

Annual and Clinical Meetings

Following consideration of a report on housing and meeting room facilities of several cities, the Board of Trustees recommends to the House of Delegates that Chicago be selected as the site for the 1962 Annual Meeting and that the week of June 11-15 be chosen as the date.

The following places and dates have previously been approved for Annual and Clinical Meetings of the Association:

Annual Meetings:
  1960—Miami Beach, June 13-17
  1961—New York, June 26-30
Clinical Meetings:
  1959—Dallas, Texas, Dec. 1-4
  1960—Washington, D. C., Nov. 29-Dec. 2
  1961—Denver, Nov. 28-Dec. 1
  1962—Los Angeles, Nov. 26-30

ACCOUNTANTS' REPORT

The Board of Trustees,
American Medical Association:

We have examined the statement of assets, liabilities, and fund balance of American Medical Association as of December 31, 1958 and the related statement of income and fund balance for the year then ended. Our examination was made in accordance with generally accepted auditing standards, and accordingly included such tests of the accounting records and such other auditing procedures as we considered necessary in the circumstances.

During the year ended December 31, 1958 certain adjustments were made to balance sheet accounts and resulted in a net charge to fund balance of $696,444. Except for $162,673 arising from revaluation of furniture and office equipment these charges resulted from changes in accounting methods. These changes, of which we approve, are more fully described in notes to financial statements and were adopted to provide more effective budgetary control over certain operations and to more fairly present the financial position and results of operations in conformity with the objectives of the Association.

In our opinion, with the foregoing explanation, the accompanying statements of assets, liabilities and fund balance and income and fund balance present fairly the financial position of American Medical Association at December 31, 1958 and results of its operations for the year then ended, in conformity with generally accepted accounting principles, which except for the changes in accounting methods referred to above, were applied on a basis consistent with that of the preceding year. Also, in our opinion, the accompanying schedule is stated fairly in all material respects when considered in conjunction with the financial statements taken as a whole.

Peat, Marwick, Mitchell & Co.

Exhibit A

STATEMENT OF ASSETS, LIABILITIES AND FUND BALANCE

Dec. 31, 1958,

with Comparative Figures for 1957

Assets	1958	1957
Cash	$ 179,417	$ 330,150
Accounts receivable:		
Advertising	656,737	500,744
Directory report service	9,371	20,526
Other	69,728	55,384
	$ 735,836	$ 588,654
Interest accrued on investments	$ 55,693	$ 75,927
Inventories of materials and supplies, at cost	362,199	392,715
Expenditures on publications in process (note 1)		102,947
Prepaid expenses, deposits, and advances:		
Deposits and advances	107,237	120,895
Commissions applicable to unexpired subscriptions to publications (note 1)		649,051
Insurance and other prepaid expenses	27,278	81,270
	$ 134,515	$ 851,216
Marketable securities and other investments, at cost (security values based on market quotations—1958, $10,871,267; 1957, $9,909,622—other investments based on cost) (note 2):		
United States Government securities	$ 7,863,056	$ 7,669,330
Industrial bonds	5,000	527,728
Common stocks	2,152,913	1,408,417
Other investments	320,172	46,785

1 modernization	1,000,000	1,000,000
	200,000	200,000
	1,860,000	1,860,000
	$ 3,810,000	$ 3,810,000
	$ 7,600,160	$ 7,048,514
Fund balance (Exhibit B)	$15,672,460	$15,363,951

Exhibit B

STATEMENT OF INCOME AND FUND BALANCE

Year ended Dec. 31, 1958

Income:		
Membership dues and subscriptions to periodical publications		$ 4,701,378
Advertising		7,140,320
Income from investments		451,211
Income from 20th edition directory report service and copy sales, less costs applicable thereto (note 5)		649,751
Other income		33,146
		$12,975,806
Costs, expenses, and other charges:		
Printing and publication costs of periodicals, books, and pamphlets	$ 6,688,737	
Councils, bureaus, and related activities (Schedule 1)	4,509,170	
Other expenses (including annual and interim meetings, net—$95,913)	331,149	
Excess of charges over credits in connection with the closing of the printing department (note 4)	98,660	
Contribution to American Medical Educational Foundation	100,000	11,727,716
Income in excess of costs, expenses, and other charges		$ 1,248,090
Fund balance at beginning of year		$ 7,048,514
Income in excess of costs, expenses, and other charges for the year ended December 31, 1958 (as shown above)		1,248,090
		$ 8,296,604
Adjustments—credits (charges):		
Adjustment of furniture and equipment valuations to appraisal value at December 31, 1958 (note 3)	(162,673)	
Write-off of commissions applicable to unexpired subscriptions to Today's Health (note 1)	(717,708)	
Write-off of unearned subscriptions to the 21st edition of the Directory (note 6)	14,641	
Write-off of the provision for completion costs of cumulative index volumes to be issued (note 6)	169,296	(696,444)
Fund balance at end of year		$ 7,600,160

See accompanying notes to financial statements.

NOTES TO FINANCIAL STATEMENTS

Dec. 31, 1958

(1) Expenditures for publications in process and prepaid commissions to agents for magazine subscriptions were deferred as of Dec. 31, 1957, in the amounts of $102,947 and $649,051, respectively. In the year 1958, the Association adopted a change in method of accounting for such items with the result that prepaid publication costs and commissions to agents are not accrued at the close of the year. These changes in accounting methods were made to provide more effective budgetary control over expenditures and in recognition of the fact that in future years such expenses will be on a reasonably uniform basis when compared with related revenues. As of Dec. 31, 1958, commissions to agents on unexpired subscriptions in the amount of $717,708 were charged to fund balance. All publication costs were charged to operating expense in 1958.

(2) It is the practice of the Association to merge the investments of its restricted and unrestricted funds. The equities of funds in investments at Dec. 31, 1958 and 1957 are shown below:

	1958	1957
Unrestricted—general	$ 5,355,141	$ 4,407,260
Restricted:		
Depreciation reserve	1,176,000	1,435,000
Association reserve	350,000	350,000
Retirement reserve	400,000	400,000
Building improvement and modernization	1,000,000	1,000,000
Equipment modernization	200,000	200,000
Building replacement	1,860,000	1,860,000
	4,986,000	5,245,000
	$10,341,141	$ 9,652,260

(3) During the year 1958 detailed records of office furniture and equipment were established and coincident therewith cost or appraisal values of such property were determined by Horder's, Inc., of Chicago, Illinois and the Association. The item values so established resulted in a write down of $162,673 in office furniture and equipment.

(4) In 1956 the Association entered into contracts with printers for its periodicals, and began the closing of its printing department for such purposes. Under this program only a small service unit will be retained to accommodate needs of the administrative offices. The excess of charges over credits for the current year with respect to the closing of the printing department was $98,660.

(5) The 20th edition Directory was completed during the current year and all income and costs pertaining thereto, which had been deferred, were closed out in 1958 in conformity with the practice followed by the Association in prior years. Effective Jan. 1, 1959 the Association will no longer defer either income or expenses with respect to the directory.

(6) The net amount of $183,937, representing unexpired subscriptions to the 20th edition of the Directory and to the Quarterly Cumulative Index, less accumulated completion costs of the cumulative index was credited to fund balance at Dec. 31, 1958. This change in accounting procedure was adopted in recognition of continuous incurrence of costs on the index together with a continuous flow of subscription income throughout any given fiscal year.

(7) Because of the various changes in accounting treatment hereinbefore described, 1957 income and expense items are not wholly comparable to 1958 factors, and accordingly 1957 figures have been omitted from this report.

(8) The approximate future liability of the Association in connection with the rehabilitation of the building facility (general office headquarters) is $1,770,000 as of Dec. 31, 1958.

April 27, 1959

A. M. A. VIEWS ON S. 94

Honorable Olin D. Johnston, Chairman
Post Office and Civil Service Committee
United States Senate
Senate Office Building
Washington 25, D. C.

Dear Senator Johnston:

This letter, outlining the position and recommendations of the American Medical Association with respect to S. 94, 86th Congress, is respectfully submitted for the consideration of your committee. We are presenting our views in a written statement rather than through oral testimony because of the difficulty which we understand you have encountered in hearing all who have applied to testify. If, however, any member of the committee has specific questions which he would like to direct to the American Medical Association, be assured that we will do our best to supply an answer.

For many years the American Medical Association has been active in encouraging the extension of coverage and the improvement of benefits under Blue Cross, Blue Shield, and commercial health insurance programs. Our interest in the over-all field has included serious consideration of a health insurance program for the benefit of federal employees and their dependents. For at least the last five years we have followed closely the bills that have been introduced in Congress in this regard and have worked with the U. S. Civil Service Commission and other interested agencies inside and outside of government in an effort to devise the most satisfactory arrangement.

At its meeting on March 19-20, 1955, our Board of Trustees voted to approve legislation which would authorize the Civil Service Commission to make available, on a voluntary contributory basis, group hospital, surgical, medical, and other personal health benefits for civilian officers and employees in the federal service. This is still the official position of the Association.

As a result of a more detailed consideration of pending legislation by our Council on Medical Service and our Council on Legislative Activities, it has been suggested that the plan finally agreed upon should (a) permit a realistic choice of plan on the part of the individual employee; (b) permit all qualified carriers to offer coverage; (c) require financial participation by the employee in the payment of premiums under any plan or plans selected; (d) provide for a minimum of governmental regulatory authority over participating carriers or plans; and (e) provide for adequate pre-funding for persons who retire after July 1, 1959, and a method by which the person who retired before that date can participate on a contributory basis.

It is our further belief, however, that the American Medical Association should not attempt to offer suggestions as to (a) the specific amount of the government contribution to the program; (b) the maximum benefits payable under the basic or major medical program; or (c) the formula to be applied in determining the eligibility of an insurer to participate in underwriting basic or major medical benefits.

In applying these policy statements to S. 94, the pending bill, it is our belief that satisfactory amendments could be made rather easily within the framework of this legislation. Without suggesting specific amendatory language we would recommend that further consideration be given to the following provisions of the bill:

Sections 5 and 6.—These sections describe the basic health plans and the major medical benefits covered by the bill.

Although section 5 specifies that the individual employee must elect to participate under one of the four basic health plans, it is not clear whether major medical insurance coverage under section 6 would be automatic for all employees or for those who elected to participate under section 5. This should be clarified.

In our opinion a more important provision of section 6 deals with the vesting of authority in the Civil Service Commission to select "one or more insuring companies" to provide group major medical coverage. This provision, plus the assumption by the government of the entire cost of this coverage, are in our opinion the most objectionable features of the bill.

Briefly, it is our position that there should be no distinction between sections 5 and 6 insofar as free choice of carrier and employee participation in the payment of premiums is concerned. We would favor a combined basic and major medical program with an opportunity for the employee to exercise a choice in the selection of the plan and a requirement that he pay a part of the premium. This, in our opinion, would result in improved health service under a more acceptable and more easily administered program. It would also eliminate any discrimination in favor of only one or two insurers providing major medical coverage.

It is recognized that all plans providing basic benefits do not offer the supplemental or major medical coverage. In these instances the government could contract with other carriers to provide the additional major medical coverage for those persons selecting basic plans which do not in themselves provide it.

It is also possible that section 6 in referring to "insurance companies" may rule out Blue Cross and Blue Shield Plans from underwriting major medical coverage. The language should be amended.

The provisions of section 6 (c) establishing a variable deductible based on annual salary is, in our opinion, a desirable feature of the bill and should be retained. It is noted that the section is silent as to how the deductible feature will be applied for retired employees and survivors. It would seem, also, that some provision should be included in this section to delineate the maximum major medical benefits payable.

In section 5 (b) reference is made to "basic health benefits" in connection with cash indemnity plans. Since this terminology is omitted in describing the plans under section 5 (a), (c) and (d), it is not clear whether a distinction is intended. In our opinion the same or similar descriptive language in all four subsections would be preferable.

Section 10.—This section deals with the division of premium costs between the government and the employee with respect to the basic plans covered by section 5. As stated above it is our belief that the employee should also share in the cost of the major medical coverage authorized under section 6.

Section 11.—As stated earlier we believe that the program should include persons already retired and those retiring after July 1, 1959, on a contributory basis. It is probable that if this type of provision is included in the bill this section would have to be amended to provide more specifically for pre-funding and for a method of financing the benefits payable to persons who retired prior to July 1, 1959.

Sections 12 and 16.—These sections provide the commission with certain regulatory authority. It is not clear, however, whether the establishment of a medical fee schedule is intended. It is our definite recommendation that fee schedules not be established by the commission. We suggest instead that consideration be given to incorporating either in the law or administrative regulations, authorization under the major medical program for payment of a stipulated percentage of the "usual and customary" charges, which language is contained in the majority of polices providing this type of coverage.

Section 13.—It is not completely clear whether this section is intended to apply retroactivity to employees who retired before July 1, 1959. Although we recognize that such authorization would represent somewhat of a deviation from past precedents we believe that participation by these individuals on a voluntary and a contributory basis is desirable.

It is recognized that inflationary trends have made it difficult for some of these individuals to purchase medical care and hospitalization, as well as other of the basic necessities of life. Their inclusion in this legislation would provide them with a contributory mechanism for the procurement of health benefits.

In conclusion and on behalf of the American Medical Association, I would like to express our appreciation for the opportunity to present our views on S. 94, 86th Congress. If the Committee is desirous of additional comment or information, please feel free to call on us.

Sincerely yours,
/s/ F. J. L. Blasingame, M.D.
Executive Vice-president

STATEMENT TO HOUSE OF REPRESENTATIVES ON H. R. 5944

April 29, 1959

The Honorable Brent Spence
House of Representatives
Washington 25, D. C.

Dear Congressman Spence:

The American Medical Association was requested to comment on H. R. 5944, the "Community Facilities Act" introduced by you.

As you know, this bill is concerned with the improvement and construction of community health facilities, especially water purification and sewage treatment and disposal plants, hospitals, and nursing homes. It proposes establishment of new federal lending authority to assist local communities to finance such facilities.

The American Medical Association has taken no official action on this bill and therefore this statement is based on past actions and established policy. In line with our continuing effort to bring about better health to the nation, we agree that an effort to improve, expand, and establish needed health facilities is commendable.

The American Medical Association recognizes that community programs to protect the public health depend to an important degree on the availability of pure, uncontaminated water, and on the disposal of human and industrial waste products. Although most large cities and towns probably now conduct sanitation programs embodying these two essential services, there remain a significant number that need new or improved plants and facilities.

Hospitals and nursing homes likewise constitute essential elements in a community health program. The A. M. A. has demonstrated its continuing interest in both types of facility by supporting, since its inception, the Hill-Burton Act, and by endorsing that portion of the housing bill that provides for government guaranteed mortgage loans for proprietary nursing homes. The financing problems of the nation's hospitals in terms of construction, renovation, and repair are a continuing challenge. The A. M. A. strongly supports a rapid expansion of nursing homes, both proprietary and nonprofit.

The A. M. A. recognizes the hospitals' need for funds to finance plant and equipment for the training of many paramedical groups, especially nurses, and the housing of interns and residents.

Traditionally the A. M. A. has urged local financing of local programs. The A. M. A. is aware that some communities refuse to support a level of public expenditures sufficient to meet minimum needs.

When situations have arisen that seemed to demand federal financial participation, we have supported grant-in-aid programs administered by the Public Health Service or government guaranteed loans of the FHA type.

Yours sincerely,
F. J. L. Blasingame, M.D.
Executive Vice-president

TELECASTS FROM ATLANTIC CITY

Television viewers in New York City, Washington, D. C., and Boston will see special programs from the American Medical Association's Annual Meeting next week. The half-hour telecasts will be part of the A. M. A.'s Bulletin of the Air series which will originate live over Philadelphia's WFIL-TV at 5:30 p. m. Monday through Thursday. Videotape recordings of the Bulletin of the Air will be seen in New York Wednesday and Thursday, June 10 and 11, at 10 p. m. over WOR-TV; in Washington, D. C., Thursday and Friday, June 11 and 12, at 11 p. m. over WTTG-TV, and in Boston Thursday and Friday, June 11 and 12, at 7:30 p. m. over WBZ-TV. The programs are presented by Merck Sharp & Dohme in cooperation with the American Medical Association.

NEW A. M. A. PUBLICATIONS

A New A. M. A. leaflet entitled "As Others See Us," published by the Joint Committee on Health Problems in Education of the National Education Association, was written primarily for teen-agers. This illustrated, easy-to-read leaflet will prove valuable to doctors, educators, ministers, parents, and youth counselors for the insight it provides into the problems of adolescence. The cost of a single copy is 25 cents; quantity discounts are available.

"Old King Cold" is a shirtpocket-sized pamphlet containing suggestions that can help employees avoid the common cold, hasten recovery, and prevent complications. The cost of a single copy is 15 cents; quantity discounts are available.

These publications may be purchased from the Order Department, American Medical Association, 535 N. Dearborn St., Chicago 10.

PAMPHLET ON SCHOOL HEALTH SERVICES

A revised edition of the pamphlet "Responsibilities of State Departments of Education and Health for School Health Services" published by the Council of Chief State School Officers and the Association of State and Territorial Health Officers has just been made available. This brochure first published in 1951 has been a very useful document for physicians serving the schools, school administrators, and public health officials.

The new edition, prepared with the aid of consultants representing both medicine and education, brings up to date the recommendations of the earlier edition. The brochure is available at 35 cents per copy from the Council of Chief State School Officers, 1201 16th St. N. W., Washington 6, D. C.

YOUR MAIL ADVERTISING ADDRESS

When you change your address in your official medical records at the A. M. A., the same address change will be reported to the advertising list users who send you direct mail advertising material. If you would like to change the address at which you are receiving advertising promotion material, please notify the A. M. A. immediately.

COUNCIL ON MEDICAL SERVICE

HEALTH INSURANCE FOR THE AGED

J. F. Follmann Jr., B.S., New York

Today seven principal methods are being used by insurance companies to provide protection for the aged against the costs of medical care.[1] These methods have largely come into being in the past few years. These methods are (1) continuation of insurance on older active workers under group insurance plans; (2) continuation of group insurance on workers who retire and their dependents, generally with part or all of the premium paid by the employer; (3) continuation on an individual policy basis of coverage originally provided by group insurance, this being accomplished by conversion of the group coverage on termination of employment or membership in the insured group; (4) new issuance of group insurance on such groups of older people as associations of retired persons or employees, retired teachers and civil servants, and golden age clubs; (5) continuation into the later years of individual insurance purchased at the younger ages, including lifetime guaranteed renewable coverage; (6) new issuance of individual insurance at advanced ages; and (7) issuance of insurance that becomes paid up at age 65, thus enabling the policyholder to pay for his protection during his productive years.

Other types of health insurers use certain of these approaches and are making valuable contributions to the extension of health insurance protection to aged people. Several recent studies bear witness to both the relative recentness as well as the effectiveness of these developments.

A survey conducted by the Health Insurance Association of America, in 1957,[2] indicated that among 160 group insurance plans underwritten by eight insurance companies, which write about two-thirds of all group health insurance in the United States, 48% of the plans provided for continuation of coverage after retirement for both employees and their dependents in 1956. In 1952, only 24% of these 160 plans had the continuation of coverage provision in the policy. Thus, in four years the proportion of these group cases providing for continuation of coverage at retirement had doubled.

In New York State, between 1951 and 1956, according to a statement by the superintendent of insurance, the number of master policies providing such coverage in retirement had increased fourfold.[3] A survey conducted by the New York State Insurance Department, in 1957,[4] among all insurance companies licensed to do business in that state, showed that 63% of all group plans providing for continuation of coverage after retirement had the provision included in the policy during or subsequent to 1954. A more recent survey of 92 group insurance plans conducted by the United States Bureau of Labor Statistics in early 1958[5] indicates that 68% of the plans in early 1958 provided benefits for retired workers as compared with 54% in late 1954. In all but three of these plans, the study further indicates, the employer pays all or a large portion of the premium.

This recent trend toward providing continuation of coverage at retirement through the group mechanism will not only have a marked affect on persons reaching retirement age in the future but will also make its presence known on a more immediate basis. An informal survey of five of the leading group insurance writers reveals that about half of the employers who are currently installing retirement benefits on presently active workers also provide the coverage to former employees already retired. A relatively few years ago, most hospital expense insurance policies sold to individuals terminated at age 65. Currently, at least 29 large insurance companies offer policies which are guaranteed renewable for lifetime, and this number should multiply significantly in the near future.

Number of Aged Covered

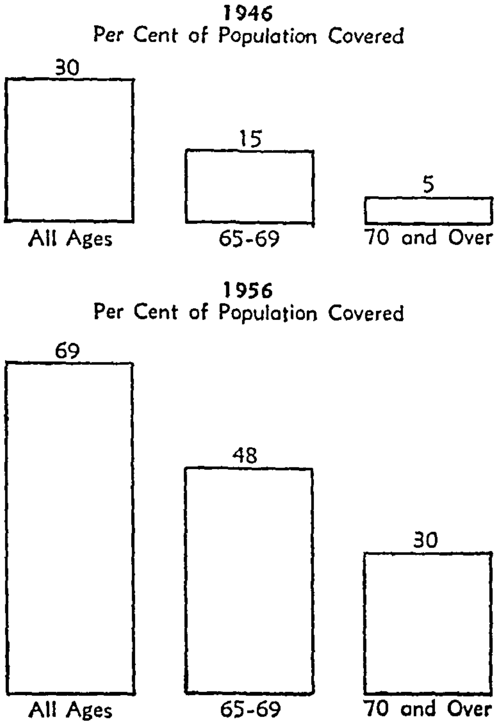
The most recent nationwide over-all estimate of the number of persons in the United States 65 years of age and older having some form of voluntary health insurance coverage was made in March, 1957, by the National Opinion Research Center—the estimate being 39% of all noninstitutionalized persons aged 65 and over.[6] It should be noted, however, that the United States Department of Health, Education, and Welfare estimates that 43% of Old-Age and Survivors Insurance (OASI) beneficiaries had some form of voluntary health insurance in the fall of 1957.[7] This study further showed that while, on the average, 43% of all OASI beneficiaries had some form of health insurance, the percentage was highest in the 65-to-69-year age group (49.5%). It was also generally higher among female beneficiaries (45.1% for all aged 65 and over), and among those beneficiaries, in turn, it was higher for single females (49.8% for all aged

---

Director, Information and Research Division, Health Insurance Association of America.

65 and over). It is noteworthy that of all OASI single female beneficiaries aged 65 to 69, 57.9% were protected by some form of voluntary health insurance; 31.7% of single female beneficiaries aged 80 and over had some form of voluntary health insurance.

However, any estimate of the number of covered aged in relation to either the total number of noninstitutionalized persons aged 65 or over in the population or to the total number of OASI beneficiaries produces an inaccurate conclusion with respect to the role being played by voluntary health insurance, since it employs a noncomparable, and hence invalid, denominator. This is so because there is a sizable percentage of the aged in either of these groupings who do not need or want, or who might consider that they do not need, health insurance protection. Their total has never been estimated with any precision. However, it is known that 18% of the aged are public welfare recipients under the federally aided public assistance programs and, as such, eligible to receive health care.[8]



Comparison of number of persons with hospital expense protection through voluntary health insurance in 1946 and 1956. Source of data is *Extent of Voluntary Health Insurance in the United States, Research and Statistics Note no. 13,* Division of Program Research, Social Security Administration Health Administration Council.

In addition, there is the unknown number of aged who, for various other reasons, do not need, want, or believe in (for religious or other reasons) health insurance coverage. These include those who receive care from the Veterans Administration, the Medicare program, the Indian Health program, or local public or private agencies; those who receive care as being totally and permanently disabled, or as being members of the armed forces, seamen, members of religious orders, or as professional courtesy; and those who have sufficient income, accumulated assets, or family resources to feel no need for insurance protection.

That these factors are real considerations in the minds of people is borne out in a 1957 public opinion study in Michigan[9] which revealed that 15% of the people not covered by a prepayment mechanism "don't think we need it." Another 17.6% "haven't got around to taking it out"; 13.9% "never gave it a thought"; and 3.2% "don't know." Still another 7% said they "don't believe in insurance"; 2.1% "get free treatment"; and 2.1% are "covered by veterans' benefits." Hence, of the people in Michigan not covered, 60.9% appear either to feel they do not need insurance or do not choose to purchase it. More pertinently, these factors are borne out by a Health Information Foundation study in 1957[6] which shows that less than 3% of aged persons interviewed had tried to buy health insurance and been turned down. More than one-fourth of the uninsured aged had never thought of getting such insurance, while twice as many said they didn't want it.

Since 2,700,000 of the aged are public welfare recipients, it would seem a conservative estimate that, of the 15 million persons aged 65 and over, 3 to 5 million do not need or want voluntary health insurance protection. Hence, with a mean of 4 million, a more proper denominator in any evaluation of the present extent of voluntary health insurance would be 11 million persons instead of 15 million. With this denominator, the adjusted estimate of the percentage of aged persons who need and want some health insurance protection, and who presently have such protection, would therefore be at least 51% as of March, 1957. As has been shown, the percentage for OASI beneficiaries would be higher.

Factors Affecting Growth of Coverage

In any consideration of the present degree of coverage of the aged, it is important to recognize that delayed reaction in the recent growth of coverage among the population under age 65 and not yet retired is inherent and that, therefore, the percentage of the aged covered in the future can safely be expected to increase. The voluntary health insurance movement is a development largely of the post–World War II period. At the beginning of 1947, for example, 30% of the population are estimated to have had some voluntary health insurance protection. A decade later this proportion had more than doubled to an estimated 70%.[10]

Today, 74% of the population under age 65 have some voluntary health insurance coverage. It would appear self-evident that the growth of coverage among persons under age 65 would bear some direct relationship to the number of the aged who will eventually be covered as those now under age 65 move into retirement. This is recognized in a recent study[7] of OASI beneficiaries made by the U. S. Department of Health, Education, and Welfare when, commenting on the generally higher rate of health insurance coverage among females, the study states that females were on the average younger than male beneficiaries and "as a result, relatively more were closer to the age when health insurance could have been attained."

This hypothesis, furthermore, is graphically demonstrated by a chart (see figure) based on a comparison of 1946 and 1956 data. From this chart it can readily be noted that the percentage of all the persons over age 70 having some form of voluntary health insurance in 1956 was exactly the same as the percentage of the entire population at all ages which was covered in 1946.

Some Recent Developments

That insurance companies have been aware of the necessity for further accelerating these developments and for moving with resolve has been exemplified by a development of marked importance during the past year. In December, 1957, the board of directors of the Health Insurance Association of America, representing 265 insurance companies writing health insurance, appointed a special committee to give thorough consideration to the entire subject of the continuation of coverage. That committee, after eight months of study, made its recommendations to the board of directors on Oct. 28, 1958. On Dec. 8, 1958, at a special meeting of the association, these recommendations were approved by the association with only one dissenting note.

The recommendations are the following: 1. Insurers should minimize refusal to renew health insurance contracts solely because of deterioration of health after issuance. 2. Insurers should promptly make available to insurable adults policies which are guaranteed renewable for life. 3. Insurers should encourage the sale of permanent health care insurance where the need exists. 4. Insurers not now doing so should promptly offer individual and family hospital, surgical, and medical care coverages to persons now over age 65. 5. It is essential that adequate voluntary health insurance be available to broad classes of physically impaired people. 6. Insurers should develop and aggressively promote soundly financed group basis coverages that will continue after retirement. 7. Insurers should encourage the inclusion in group contracts the right to convert to an individual contract on termination of employment.

An important factor which will affect the coverage of the aged in future years is the increasing public awareness of the value of voluntary health insurance protection. Today the mechanism, the facility, by which the future aged might have health insurance protection is available. This is a fact too often overlooked.

However, insurance on a voluntary basis must be purchased as a matter of free choice by individuals on their own behalf or by employers, unions, or other types of organizations. The data to which previous reference has been made indicates that this is being done to an increasing degree. Nonetheless the degree of rapidity by which this will come about is directly affected by the degree to which individuals, labor unions, or employers make their choices in relation to the available dollars and their other economic wants.

From the standpoint of the individual who is not protected as a member of a group, choice must be made between health insurance and the many appealing, often highly advertised and installment purchased, consumer goods and services. With respect to the employer, health insurance has to compete not only with all the costs of production, including wages, but with other types of fringe benefits desired or demanded by employees. Employers in America have accepted their responsibility to their employees on an increasingly generous scale, to the extent where, today, fringe benefits average some 20% of payroll.[11] The employer is also faced with the problem of the extent to which his productive employees are willing to share in the provision of benefits to the retired employees. Since he has to compete with other employers in an open labor market for his employees, this becomes an important factor. In making his choice the employer, in turn, is often governed by the contracts arrived at through collective bargaining.

Potential Rate of Increase of Voluntary Health Insurance of the Aged

End of Year	Growth in % Covered	% Covered Who Need and Want Protection
1958	4.0	55
1959	4.5	60
1960	5.0	65
1965	15.0	80
1970	>10.0	>90

Therefore, as individuals, labor unions, and employers become increasingly cognizant of the importance of health insurance protection in the later years, and since the voluntary mechanism by which this protection might be provided now exists, it is reasonable to expect that the coverage of persons over age 65 in future years will increase more rapidly than has been so in the past.

Forecast for the Future

Since the number of aged owning voluntary health insurance has increased an average of 3% each year between 1952 and 1957, the following increases in this coverage, even without further development or progress, might be expected—51% in 1957, 54% in 1958, 57% in 1959, 60% in 1960, 63% in 1961, 75% in 1965, 90% in 1970, and over 90% in 1975. For OASI beneficiaries the figures would be larger, since they commence with a greater percentage covered and since the rate of growth among these persons has been greater (3½%).[7]

However, when reasonable allowance is made for the delayed reaction inherent in the recent growth of coverage of the population under age 65, for the increasing public awareness of the value of voluntary health insurance protection, and for the very recent developments being brought about by all types of insurers and plans in an endeavor to make voluntary health insurance available to all present and future retired persons who need and want such protection, it would follow that the potential rate of increase would exceed this base line and that the excess itself would increase for several years. Therefore, a conservative estimate of the potential of voluntary health insurance in assisting persons 65 years of age and older to meet the costs of hospital and medical care should, all other things being equal, approximate that shown in the table.

HEALTH-WELFARE PARTNERSHIP

David E. Price, Washington, D. C.

For the health professions, homemaker services offer a quick lift in an overburdened time. We, in public health, are concerned with the general well-being of people, the healthy tone of family life, as well as the specific physical health of individuals; and so we are particularly involved in the needs of the chronically ill. Their long-term illnesses trap whole families, affecting the well in addition to the sick, threatening established ways of life, draining finances, wearing out affection.

The Homemaker

We are keenly interested in homemaker services because we know that the homemaker can do much to mitigate these effects. The physician is trained to serve the sick individual, but a homemaker is trained to serve the entire family. She cannot replace a physician—but by the same token, a physician cannot replace her. For many families, she brings new hope.

The mutual interest of the health and welfare professions in extending homemaker services affords a good illustration of how closely health change and social change bind us in inextricable partnership. The longer life span—a health gain—has given us an older population with consequent increase in chronic ills. These long-term disabilities in turn bring economic and emotional problems which can lead to more physical illness. Smaller families, working wives, and the change to an urban, apartment civilization—a social change—often give us no one to care for the bedridden and homebound. And so it goes, round and round—health-welfare, welfare-health. In the middle stands the homemaker, a personification of our partnership.

Chief, Bureau of State Services; Assistant Surgeon General, Public Health Service; United States Department of Health, Education, and Welfare.

Read before the National Conference on Homemaker Services, Edgewater Beach Hotel, Chicago, Feb. 10, 1959.

The aid she can give—in the freeing of nurses for more urgent professional concerns and the release of hospital and nursing home beds and facilities —is of practical value and great importance.

But, over and above this, it is the freeing of a patient's mind from fears of forced absence from family or confinement in an institution and the assistance given to families in bearing burdens of care beyond their strength which are of greatest national therapeutic good.

Although there are not enough homemakers today, there is no shortage in the reserve from which they can be drawn. There are thousands of mature women—warm, stable, intelligent—who can be recruited and trained; who will be eager to be trained; and for whom such employment will also be an answer.

Nor is there any long-term training period necessary. The preparation should be thorough, but it is not the year after year, costly education needed for doctor or nurse. Homemakers already know how to "make a home" from having made their own, how to tend children from tending theirs, how to be thoughtful and friendly, because they themselves have been lonely on occasion.

Agency training courses for homemakers vary widely in length, scope, and adequacy. In general, they seek to teach any special skills the homemaker may need. We hope that increasingly such training will include simple bedside home care, nutrition, infant care, and assistance in rehabilitation procedures. To encourage this trend, the Public Health Service has prepared a fact sheet dealing with specialized problems in home care of the chronically ill, which may have guide-line value for agencies developing homemaker training programs. In addition, with assistance from the American Medical Association and other groups, we have prepared a booklet, "Strike Back at Stroke." It is designed for doctors to use in training homemakers and other lay persons who can assist patients in the exercises necessary for rehabilitation after stroke.

Homemaker Services

State-Sponsored Services.—The need for health emphasis in homemaker training is highlighted in a study [1] made by the Public Health Service in preparation for this conference. This study reveals that 93% of the families receiving homemaker services during the study week in 1958 either had a sick member or members of the family in the home or needed a homemaker because of the absence of a member of the family who was hospitalized.

A number of state health departments are showing courage and enterprise in devising new programs. New Jersey has made a notable record in just this sort of pioneering with its community homemaker services. We in the Public Health Service wish more would do the same sort of thing.

In the fall of 1950, a homemaker service specifically designed to meet the needs of long-term patients was started in Essex County, New Jersey. It stimulated great interest throughout the state, and in 1952 when the Prevention of Chronic Illness Act became law in New Jersey, it contained a provision requiring the state department of health to "plan for . . . adequate visiting nurse and housekeeping aid services by appropriate public or private agencies throughout the State to the end that the nursing and medical care being furnished the chronic sick in their own homes shall be improved in every manner possible."

A State Consultant Committee on Community Homemaker Service was established to carry out this requirement through a cooperative program with community groups and the department of health. The Medical Society of New Jersey and its county societies gave endorsement and support.

Now, five years later, there are 11 autonomous voluntary community homemaker services in New Jersey—three of them established during the year just passed. They make community homemaker service available to one-half of the state, geographically, and serve more than half the population. Activities of planning committees in the state foreshadow the establishment of several more services this year.

The state health department carries all training costs through financial assistance to the extension division of Rutgers, the state university. Five hundred seventy-five homemakers have been trained—a figure equaling one-third of the national total of all homemakers reported in voluntary and public homemaker programs last year.

In the report [2] of this statewide program, there are words of real import,[3] unusual in an official document—"joy," "delight," "satisfaction," and "thrilling"—words which illumine the enthusiasm, enterprise, and teamwork that have made the New Jersey program not only possible but outstandingly successful. The part being played in the National Conference on Homemaker Services by the American Medical Association gives promise that other state medical societies may follow the New Jersey example.

Voluntary Services.—Representatives of national health organizations, co-sponsoring this conference have worked hard—in preconference study groups and planning committees—to make this a truly forward-looking, stimulating call for action. They are not all agreed on definition of terms, procedures, potentials, or guidelines. And that is fine, because too early and easy an agreement can deaden initiative and imagination. They are all agreed, however, that there must be definitions, procedures, and guidelines—though not necessarily any single method or procedure. The homemaker program is one that has developed in a variety of ways. And that is good, because it is a program of, and for, human beings whose greatest claim to humanity is divergence. The homemaker program can continue to develop in various ways and under various auspices.

Each of the national voluntary agencies has contributed much to the present development of homemaker services. Some have helped by providing training, some by organizing new services, and some by financing community programs. For example, the National Foundation has, of course, long maintained a home attendant program for thousands of poliomyelitis patients—differing in many ways from the usual homemaker services organized on a community basis, but rich in experience. It also purchases homemaker service from a number of programs.

The American Heart Association carries on an extensive national program of training in work simplification for homebound cardiac patients. Its local chapters participate in homemaker programs in many ways. In St. Mary's County, Md., for example, the association has given financial assistance to expand services, paying housekeeping aides in homes for patients with cardiac disease when there are no other available funds. In Chicago the local association gave funds to the Cook County Hospital for a home case demonstration program, including homemaker services.

In at least 21 of the American Cancer Society's 60 divisions, there is already some type of activity involving homemaker service—usually referred to as housekeeping assistance. They train and supervise housekeeping volunteers of their own and also contribute to the financial support of other agencies for their homemaking programs.

The National Tuberculosis Association is deeply interested in homemaker services, since a majority of tuberculous patients within the 25-to-45-year range are women—many of them responsible for families. The association is aware—as we are in the Public Health Service—that at the present time many existing homemaker programs utilize criteria which are restrictive in meeting the needs of long-term patients. It hopes to be able to promote greater understanding of the importance of developing long-term services. Several homemaker programs receive substantial grants for the care of tuberculous patients from the NTA.

The National Health Council has told us that it is looking forward to a new health career category coming out of this conference, and so it urges upon us the necessity of developing a clear definition of homemaker services and programs. Here you see an invaluable marshaling of interest and aid, a vast reservoir of assistance. There is need for truly ingrained teamwork at this national level in order to pave the way for cooperation at all levels. Of course, most important of all is the local level.

Community-Sponsored Services.—In a cooperative venture in New York City, homemaker services were developed as a natural extension of hospital services.[4] This is the work of the Jewish Family Service which serves Manhattan, the Bronx, and Brooklyn. It provides homemaker services to its own clients on the usual family casework plan, but in addition it makes homemakers available to three hospitals—Beth Israel, Hillside, and Mount Sinai; to the Altro Health and Rehabilitation Service; and to the home-care project of the Central Bureau for the Jewish Aged. It employs, trains, and pays these homemakers and then turns them over to the hospitals' medical-social workers to supervise in a medically focused program.

Often homemaker service plays an essential part in carrying out the goals of comprehensive medical treatment and care for the family until the patient reaches normal or optimum functioning. But if a family has to apply to one agency for homemaker services, in order to carry out another agency's medical care treatment, a bottleneck in the provision of services can result.

Realization of the waste involved for patient, family, caseworker, and administrative staff in this duplication led to the establishment of the present integrated program in New York. It has been achieved with no increase in cost and provides more satisfactory service. Hospitals in other communities might well consider the feasibility of similar arrangements, particularly in connection with their home-care programs.

In Detroit; Omaha; Syracuse, N. Y.; and New Canaan, Conn., visiting nurse associations provide another type of medically supervised homekeeping. Faced with inadequate community resources, the Visiting Nurse Association in Detroit, for example, established its own homemaker service in 1955, employing 30 home aides.[5] It has a daily census of 1,000 patients with chronic or long-term conditions from whom to select candidates for home aide service. Obviously it needs more aides. A count taken on a single day last year showed 325 patients between the ages of 75 and 95. Only eight had received home aide service that day.

The strength of the program is the teamwork of the family, the professional nurse, the home aide, and the fact that the resources of the agency are available to the aides. Three years' experience have convinced the professional staff that this service has increased the usefulness of the visiting nurse and is a vital part of any home-care program.

Conclusions

These then are some of the hopeful ways homemaker services have been developing in health-related settings. I wish there were more of them. I hope there soon will be. They are not, of course, a panacea, but I can really see no end in sight to the needs for homemaker services or the gratitude they can earn from families and the health and welfare professions.

But there are so few homemakers. In 1957, 14,000 families were served by them—only 14,000 out of the estimated 43 million families in the United States.[6] Today, 153 agencies report homemaker service programs, but how many homemakers does this mean? Some programs have only one or two! Last year, there were only some 1,800 listed in the whole country. Report after report coming in to us in preconference material read, "We can serve only one-third of our applicants," "We are not meeting the real needs of the community," "We have to turn down 60% of our applicants."

Why? With everyone in favor? Because no one is opposed, do we sit back and think these services will come into being simply, easily, of their own accord? They won't. It takes at least a year of planning, negotiating, and arranging to establish a new homemaker service—and this after preliminary years of basic preparation.

We, in health and social fields, see the people who need these services as individuals, and we know how great is their need. We would not sign the commitment papers that separate an old couple, because we know it could easily be a death warrant. We would not be responsible for taking the child away from the widower father, because we see not only the end of a family but the intensification of tragedy for the child. We are automatically in favor of homemaker service that can prevent separation, because we know.

But for too many other people these things happen out of sight and without their knowledge. It is not enough for us to see them, we must make others see also, not in statistics or as caseloads or diagnoses, but in human terms. We must make people see the need and see the hope.

Let us stop thinking it will be easy, and let us work hard. Let us stop congratulating ourselves that it will be a cinch to recruit homemakers; let us start recruiting them. As Kingsley says, "Let us do lovely things all day long—not dream them." For the gifts of hope and dignity and surcease are lovely things indeed—things with glory about them.

We must be flexible. We must be inventive. We must be realistic. It will cost money; and yet we can point out that costs of homemaker services would have to go for other, less satisfactory services, if the homemakers did not exist. For example, Colorado reports 69 children cared for in their own homes by 13 homemakers during one month at a cost of $1,400.[7] Had they been placed in foster homes, the minimum boarding cost would have amounted to $4,100. Moreover, establishment of homemaker services requires no financial outlay for buildings, grounds, and maintenance.

A vital question to be considered at this conference concerns the financial status of the family served. Even the well-to-do may not know where to go or, indeed, have anywhere to go to find the kind of help needed in a family emergency. There is a great deal of difference between trying to hire a maid, hoping desperately that she will stay in spite of difficulties and health emergency in the family, and in welcoming a trained person coming into the home because of these very difficulties and disruptions. The homemaker is guaranteed in advance, backed by a reliable community agency of fine reputation, with casework and counseling available if needed. Homemaker service therefore should not be restricted to any economic group. Of course, if the family can pay for the service, it should.

To be of use to us in the health field, particularly with the handicapped and chronically ill, there should be no restrictive time limit placed on length of continuing service. It is long-term care that can offer so much in health gain and restoration of self-sufficiency to a patient suffering from the handicapping results of stroke, heart disease, tuberculosis, poliomyelitis, severe diabetes, or accident. If the long hours between visits of doctors, nurses, and physical therapists are wasted, the patient wastes also, in a sort of twilight, vegetative existence.

But if there can be someone present to prompt and encourage during part of these hours, the time becomes a time of practice and achievement which can return the patient truly to life. This kind of priceless companionship is being given by homemakers today and could be given in many more homes.

As chief of a bureau which works directly with the states, I have noted a growing trend in health departments toward a research approach to public health practice. We are encouraging this in every way possible. At the state and local level they are seeking fresh ways of meeting health needs, trying to fit methods to people rather than forcing people into rigid patterns of established procedure. In such a search, homemaker services should prove of interest to many.

The surgeon general has asked me to express his deep personal interest and to assure you that the Public Health Service will give all possible assistance to the advancement of homemaker programs.

MEDICAL NEWS

CALIFORNIA

Dr. Lederberg Gives Nobel Lecture.—Joshua Lederberg, Ph.D., head, department of genetics, Stanford University School of Medicine, co-winner of the 1958 Nobel Prize for Medicine, delivered his Nobel Prize Lecture in Stockholm May 29 on "Genetic Recombination." Dr. Lederberg will give other lectures in Scandinavia and elsewhere while abroad, and will visit former colleagues in laboratories at Copenhagen, Milan, Paris, and London.

Dr. Kaplan Named Cancer Award Recipient.—Dr. Henry S. Kaplan was named the recipient of the second annual award "for meritorious investigation by a scientist under the age of 45, in the field of cancer," awarded by the Ann Langer Cancer Research Foundation of Chicago. Over $115,000 has been contributed by the foundation to the University of Chicago, Michael Reese Hospital, and Mount Sinai Hospital in Chicago and Hebrew University in Israel for cancer research work. The award is supported by the family of the late Bertha Goldblatt Teplitz for whom the award is named. Dr. Kaplan, professor of radiology, Stanford University Medical School, received the award "for his significant contributions to the field of both basic and clinical cancer research." He has been the director, Biophysics Laboratory, Stanford University, since 1958.

Campaign Against Accidental Poisoning.—Members of the Alameda-Contra Costa Medical Association Child Welfare Committee have started a campaign aimed at reducing the number of child poisoning cases in the San Leandro-Hayward area. The association is distributing 50,000 notices to parents of school children which point out that in the South County area there are 35 child-poison cases per 10,000 residents as compared with 16 per 10,000 in the remaining Alameda-Contra Costa communities. The two-year child-injury survey (1957-1958) of the association has indicated that each week 54 children are taken to East Bay hospitals because they swallowed a poison product. The survey showed that the 2-year-old child is most often involved in accidental poisoning, and medicines, especially aspirin, are most frequently ingested. Petroleum products—paints, kerosene and thinners—are the second most common cause of child poisoning, with insecticides and fertilizers the third most frequent poison ingested. In 1958, there were 2,303 cases of child poisoning seen in the 23 East Bay hospitals participating in the study. The association's program has been joined by the Bureau of Maternal and Child Health of the State Department of Public Health, which has begun a three-year study on epidemiology of childhood injuries.

FLORIDA

Dermatologist Receives Award.—Dr. J. G. Smith Jr., assistant professor of dermatology, University of Miami School of Medicine, Coral Gables, received the annual award of the American Dermatologic Association at the association's annual meeting in Atlantic City "for his studies on 'The Aged Human Sebaceous Gland.'" Dr. Smith's studies show that lowering of sebum excretion in the aged female with resulting aging of the skin, is related to the decrease in size and function of the sebaceous gland in women after the menopause. No such change occurs in the aging male.

ILLINOIS

Chicago

Plans for New Hospital and School Buildings.—Mercy Hospital and Loyola University's Stritch School of Medicine disclosed future plans of the two institutions. Mercy will build a new hospital near its present location at 26th and Prairie Avenue; Loyola is studying various proposals for a new medical school building to replace its present structure in the West Side Medical Center. Mercy Hospital, the main teaching hospital for the Stritch School of Medicine, was founded in 1851. The two institutions jointly operate an out-patient clinic at Mercy providing more than 60,000 patient visits annually. Department chairmen at the school have also headed the hospital departments. In 1954, Mercy and Loyola expressed interest in constructing a teaching hospital and medical school near Skokie. The decision of Mercy Hospital to continue to serve the south side "presents Loyola with an opportunity to study various proposals for a new medical school building and teaching hospital." Meanwhile the present affiliation arrangements will continue. A 19-man faculty committee has been appointed to study proposals. Dr. John J. Madden, chairman of neurology, and Dr. James J. Callahan, chairman of bone and joint surgery, will lead the group in gathering proposals for a new medical school building from alumni and faculty.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

MASSACHUSETTS

State Medical Election.—Dr. Lawrence R. Dame, of Greenfield, was named president of the *Massachusetts* Medical Society, succeeding Dr. Charles C. Lund, of Brookline. Other officers elected include Drs. Carl Bearse, Cambridge, president-elect; John C. Corrigan, Fall River, vice-president; Robert W. Buck, Waban, secretary; Eliot Hubbard Jr., Cambridge, treasurer; Norman A. Welch, West Roxbury, assistant treasurer; and Max Ritvo, Brookline, orator.

Dr. McKittrick Honored.—Dr. Leland S. McKittrick, professor of clinical surgery, Harvard University School of Medicine, Boston, received the first alumni citation to a University of Wisconsin medical graduate for "distinction in medicine" at the Medical School's Alumni Day banquet, May 15. In 1950-51, Dr. McKittrick was president of the Massachusetts Medical Society, and from 1951-58 he was a member of the board of regents of the American College of Surgeons. He is chairman of the Council on Medical Education and Hospitals, A. M. A.

MICHIGAN

Hospital Lecture.—Dr. Richard H. Lyons, professor of medicine, State University of New York Upstate Medical College at Syracuse, and former medical director of Wayne County General Hospital, will address the medical staff and the medical alumni of Wayne County General Hospital in the Gruber Auditorium, Eloise, on Wednesday, June 17, 4:30 p. m., on "The Role of the Modern Hospital in Medical Education." The lecture will be followed by the annual dinner of the medical staff at the Hawthorne Valley Country Club.

MINNESOTA

British Lecturer.—Dr. Roderic A. Gregory, professor of physiology in the University of Liverpool, England, gave a lecture on "Physiological Mechanisms of Gastric Secretion" at the Mayo Foundation, Rochester, April 23.

Dr. Love Named President of Cushing Society.—Dr. J. Grafton Love, head, section of neurologic surgery, Mayo Clinic, Rochester, was elected president of the Harvey Cushing Society at the annual meeting in New Orleans, and Dr. Hendrik J. Svien, a member of the section, was elected secretary of the society for a three-year term. Dr. Love will take office in 1961. Dr. Svien previously had been treasurer of the organization. The Harvey Cushing Society has about 700 members, and reportedly is the largest neurosurgical group in the world. It was founded in 1931 and was named in honor of Dr. Harvey Cushing, American neurosurgeon. The objectives of the society are to promote the study and advancement of neurologic surgery and allied subjects related to organic neurology.

NEW HAMPSHIRE

Annual Research Conferences.—The 1959 Gordon *Research Conferences* will be held June 15-Sept. 4 at Colby Junior College, New London; New Hampton School, New Hampton; and Kimball Union Academy, Meriden. The conferences were established "to stimulate research in universities, research foundations, and industrial laboratories." They consist of an informal type of meeting and discussion groups. Meetings are held in the morning and in the evening, Monday through Friday, with the exception of Friday evening. The primary purpose of the program is "to bring experts up to date on latest developments, to analyze the significance of these developments, and to provoke suggestions concerning the underlying theories and methods of approach for making new progress." Attendance is by *application and advanced registration is* required, with a deposit of $15. Fee for attendance is $100. For information write Mr. W. George Parks, Director, Gordon Research Conferences, University of Rhode Island, Kingston, R. I.

NEW YORK

New York City

British Lecturer.—Dr. Kenneth S. Smith, editor-in-chief of the *British Heart Journal* and president of the Life Assurance Medical Society of Great Britain, was guest lecturer at the State University of New *York Downstate Medical Center in Brooklyn*, May 15. Dr. Smith spoke on "Heart Disease and Life Assurance as Related to the New Outlook in Coronary and Hypertensive Disease."

University News.—Dr. Karl Harpuder, attending physician in charge of physical medicine and rehabilitation at Montefiore Hospital in the Bronx, formerly of Munich, Germany, was the second Louis J. Horowitz visiting professor in the department of physical medicine and rehabilitation, New York University–Bellevue Medical Center. The Louis J. Horowitz visiting professorship was created to honor the late Mr. Horowitz, one of the original founders of the Medical Center's Institute of Physical Medicine and Rehabilitation. He contributed and bequeathed about 12 million dollars to the institute since its opening in 1948.——Bernard L. Oser, Ph.D., president and director, Food and Drug Research Laboratoriees, Inc., was appointed a lecturer on the faculty of Columbia University in the Institute of Nutrition Sciences, School of Public Health and Administrative Medicine. Beginning with the spring semester in February, he will give a course of lectures to graduate students on food regulation and safety evaluation.

Fellowship in Medical Neoplasia.—Memorial Center for Cancer and Allied Diseases, training center affiliated with Cornell University Medical College specializing in cancer and allied diseases, announced the offer of special fellowships for study to a limited number of graduate physicians. The purpose and scope of the program is to offer physicians trained in internal medicine the opportunities available at Memorial Center. Activities of the fellow include (1) study of a problem under supervision, to be carried out under the aegis of the lymphoma service of the department of medicine; (2) attendance at a weekly service teaching conference, and medical grand rounds; (3) assignment to surgical clinics and conferences; (4) the integrated study of the hematology and pathology of cancer; (5) observation of the role of the medical consultant to patients undergoing radical surgery for cancer; and (6) opportunity to study the management of patients with lymphomas, leukemias, and allied diseases. Candidates must be graduates of recognized A. M. A. approved medical schools, must have completed or be in process of completing two years of postgraduate training in internal medicine, and must be "of the highest integrity and moral character" and have an expressed interest, both academic and clinical, in the study of malignant neoplastic diseases. The salary stipend is $6,000 a year without maintenance. Appointment is for one year normally beginning July first, renewable for one or two years. Applicants should apply in writing to Dr. Henry D. Diamond, Chief, Lymphoma Service, Department of Medicine, Memorial Center for Cancer and Allied Diseases, 444 E. 68th St., New York 21.

NORTH CAROLINA

Hospital Blood Bank Licensed.—For the first time, a hospital blood bank in North Carolina has been licensed by the Division of Biologics Standards of the National Institutes of Health of the U.S. Public Health Service. The blood bank is that of N. C. Memorial Hospital at the University of North Carolina, Chapel Hill. This accreditation allows N. C. Memorial Hospital to ship blood outside of the state. The blood bank is closely connected with the basic science program of the UNC School of Medicine. The hospital blood bank is directed by Dr. Robert D. Langdell and Dr. Warner L. Wells, faculty members of the School of Medicine.

Study on Choice of Specialties.—The School of Public Health of the University of North Carolina, Chapel Hill, is collecting data from a national sample of physicians in various specialties. The purpose of the study is to identify factors motivating physicians in their selection of particular fields of practice. Data have already been collected from more than 2,600 medical students in a national sample of 10 medical schools. This will be correlated with the information collected from physicians to try to bring out factors operating at various stages of their careers to cause physicians to choose a specialty or general practice. Of particular interest are those specialties in which there is a shortage of physicians such as pathology, public health, and psychiatry. The study now in its third year is expected to last two more years and is supported by a grant from the National Institutes of Health.

Conference of Thai Medical Educators.—The Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, will be host for a three-day conference of all Thai medical educators currently in the United States, beginning on Tuesday, June 9. This workshop in medical education is being jointly sponsored by the China Medical Board of New York, Inc., and the International Cooperation Administration. Dr. Robert W. Prichard, associate professor of pathology, is local chairman for the conference. The meeting is planned and organized primarily for faculty members of two existing Thai medical schools studying American medical education methods. Topics to be discussed will include "The Aims and Objectives of Medical Education," "The Structure and Functions of a Medical School," "The Teacher and the Curriculum," "The Medical Student," and "The Challenge of a New Medical School." The China Medical Board of New York, Inc., will be represented by Dr. Harold Loucks, director, and Dr. Oliver R. McCoy, associate director. The International Cooperation Administration representative will be Dr. E. Harold Hinman, former dean, University of Puerto Rico School of Medicine, San Juan, now chief, Health Resources Staff, Public Health Division. Other participants are: Dr. George T. Harrell Jr., dean, University of Florida College of Medicine; Dr. Howard A. Kline, chief, Education and Training Branch, Division of International Health, U. S. Public Health Service; Dr. Robert A. Moore, president, State University of New York Downstate Medical Center; and Mr. Daniel D. Swinney, training officer, Education and Training Branch, Division of International Health, U. S. Public Health Service.

PENNSYLVANIA

Philadelphia

Dr. Alpers Honored.—Dr. Bernard J. Alpers, head, department of neurology, Jefferson Medical College, was honored May 15, when an oil portrait of him donated by the senior class was accepted for permanent exhibition. A past-president of the American Neurological Association, he is author of "Clinical Neurology."

Dr. Fay Named College President.—Marion S. Fay, Ph.D., has been named president of the Woman's Medical College of Pennsylvania, effective May 1. Dr. Fay joined the faculty of the Woman's Medical College in 1935 as professor of physiological chemistry. In 1943, she became acting dean and in 1946 was named dean of the college. She will continue the duties of dean.

Student Wins Essay Competition.—At the annual meeting of the New Jersey Chapter of the American College of Chest Physicians, Mr. Garret M. Keating, a senior medical student from Hahnemann Medical College was awarded first prize for the "best essay on chest diseases." Competition included senior medical students from New Jersey in any medical school in this country and abroad. His article was "A Review of Injuries to the Thorax: Their Classification and Early Management."

Residency in Pediatric Pathology.—The department of pathologic anatomy of The Children's Hospital of Philadelphia announced that preparations were made to offer a year of residency training in pediatric pathologic anatomy to residents in general pathology completing their second year of formal training in pathologic anatomy. The year of training is approved by the American Board of Pathology toward eligibility for examination by that board. It is anticipated that appointments will be made to begin, generally, about July 1 of each year. Interested physicians should make application to Dr. William C. Yakovac, Director of Pathology, The Children's Hospital of Philadelphia, 1740 Bainbridge St., Philadelphia 46.

SOUTH CAROLINA

Dr. Lynch Honored.—The Alumni Association of the Medical College of South Carolina honored Dr. Kenneth Lynch, president of the college May 13 at Columbia during the state medical meeting. Dr. Lynch has practiced medicine for a half century. Dr. Keitt H. Smith is president of the Alumni Association.

TENNESSEE

State Medical Election.—The following officers of the Tennessee State Medical Association were elected April 14 to serve until April 10, 1960: Dr. Harmon L. Monroe, Erwin, president; Dr. Ralph O. Rychener, Memphis, president-elect; Dr. Rudolph H. Kampmeier, Nashville, secretary-editor; and Mr. J. E. Ballentine, 112 Louise Ave., Nashville 5, Tenn., executive director.

GENERAL

Change of Address.—The Joint Commission on Accreditation of Hospitals has announced that effective May 8, the offices of the commission will be moved from 660 N. Rush St., Chicago 11, to 200 E. Ohio St., Chicago 11.

Pediatric Meeting in Sun Valley.—The Intermountain Pediatric Society will hold its annual meeting at Sun Valley, Idaho, June 26-28. The program will be presented by the following speakers: Drs. Robert H. Alway, San Francisco; Marion E. Lahey, Cincinnati; Ralph V. Platou, New Orleans; and Josef Warkany, Cincinnati. Sessions will be held daily from 8:00 a. m. until noon; round-table luncheons from noon until 1:30 p. m. The meeting is open to all physicians. For information write to the Intermountain Pediatric Society, 2000 S. 9th E., Salt Lake City, Utah.

Proctologists Convene in Atlantic City.—The 58th annual meeting of the American Proctologic Society will be held June 15-17 at the Shelburne Hotel, Atlantic City, N. J. Dr. Karl Zimmerman, Pittsburgh, will present the presidential address at the opening session. Six panel discussions and 12 postgraduate discussion groups are planned. Two symposiums are planned with the following titles and moderators: "The Future of the Practice of Medicine," Dr. Con Amore V. Burt, New York City, and "Ano-Rectal Surgery," Dr. Patrick H. Hanley, New Orleans. A program of exhibits and scientific motion pictures is arranged. The banquet is planned for June 17, 7 p. m. For information write Dr. Norman D. Nigro, 10 Peterboro, Detroit 1, Secretary.

Meeting on Biological Psychiatry.—The 14th annual convention of the Society of Biological Psychiatry will be held June 12-14 at the Claridge Hotel, Atlantic City, N. J., under the presidency of Dr. Joseph Wortis, Brooklyn. Three round-table luncheons are planned: "Toxic Theories of Schizophrenia," "Methodological Problems in Neuropharmacological Research," and "The Significance of Gamma-amino Butyric Acid (GABA) in the Brain." Thirty papers are scheduled for presentation, including "Further Studies on the Use of the Nucleic Acids (Ribonucleic Acid) in the Treatment of Impairment of the Retention Phase of Memory in Aged Individuals," by Dr. D. Ewen Cameron, Montreal, Canada, and "The Reflex Mechanisms of Habituation," by Dr. Eugene Sokolov, University of Moscow, U. S. S. R. A motion-picture program is planned. The annual banquet will be held June 14, 8 p. m. For information write Dr. George N. Thompson, 2010 Wilshire Blvd., Los Angeles 57, Secretary-Treasurer.

Library Association Meeting.—The Medical Library Association will hold its annual meeting June 15-19 at the King Edward Sheraton Hotel, Toronto, Canada. The story of the discovery of insulin by Drs. Banting and Best will be recreated by Dr. William R. Feasby, professor of the history of medicine, University of Toronto. Dr. James K. W. Ferguson, director of the Connaught Medical Research Laboratories, will discuss "Medical Research in Canada." Other speakers include Dr. R. Ian Macdonald and Dr. Stuart D. Gordon who will speak on "Canadian Milestones in Clinical Medicine and

Surgery." Dr. William Boyd will give the banquet address entitled "On Words." Meetings will include a talk by Mr. Scott Adams on activities of the office of science information services and panel discussions on cooperative control of library resources and the medical editor, author, and librarian as a team. The conference will be preceded on Saturday, June 13, by refresher courses on medical library practice.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases occurred in the United States, its territories and possessions in the weeks ended as indicated.

Ground-Breaking for Library of Medicine.—Ground-breaking ceremonies for the National Library of Medicine will be held at the National Institutes of Health, Bethesda, Md., June 12, 2:30 p. m. Dr. Champ Lyons, chairman, National Library Medical Board of Regents, will preside. Secretary of the Department of Health, Education, and Welfare Arthur S. Flemming, will give an address, and Senator Lister Hill, of Alabama, will turn over the first spade of earth. The library was founded in 1836 by Joseph Lovell, surgeon-general of the United States Army, as the Library of the Surgeon-General's Office. It was developed as a national resource under John Shaw Billings, librarian from 1865 to 1895. In 1922 it was designated the Army Medical Library and in 1952 was renamed Armed Forces Medical Library. In 1956, by terms of Public Law 941, 84th Congress, the library was transferred to the Public Health Service, Department of Health, Education, and Welfare, as the National Library of Medicine. It will be completed in 1961, the 125th anniversary of its founding.

Health Institute in Providence.—On June 17-18 the 25th New England Health Institute will be held at Providence College, Providence, R. I. Presiding at the opening general session will be Dr. Jeremiah A. Dailey, director, Rhode Island Department of Health. Following luncheon, June 17, five groups will be formed developing topics as follows:

Maternal-Infant Health—"Preface to Life" and "Exploring the Baby's World."
Child Health—"Search Begins for Lost 'Normal' Child."
Adult Health—"Meeting the Challenge of Maturity."
Laboratory Section—"Fluorescent Antibody Techniques."
Environmental Sanitation Section—"Control of Additives Used in the Food Industry" and "Anticipated Problems in the Milk Industry."

At the banquet June 17 Prof. William M. Stewart, of Northeastern University, Boston, will speak on "Your Only Problem is People." The closing session will be presided over by Dr. Stanley H. Osborn, commissioner of health, Connecticut State Department of Health. A panel, "Making the Most of What We Have," is planned. Dr. Albert L. Chapman, assistant surgeon general, U. S. Public Health Service, will speak on "Springboard for the Future." Registration fee is $3.

Study in Population Trends.—Better to understand the birth rate, reportedly the most unpredictable component in population growth, scientists at Miami University, Oxford, Ohio, plan a second national study to compare actual childbearing experience with wives' expectations five years earlier, and to assess any changes in wives' plans and attitudes. A Rockefeller Foundation grant of $219,000 to the university will help support the research at the Scripps Foundation for Research in Population Problems over a four-year period. In the first national survey, made in 1955, information was sought of a group of married women of childbearing age concerning the number of children they expected to have and the factors influencing their decisions on family size. The survey data revealed that family limitation was almost universally approved by younger couples of the white population; that physical defects played only a small part in average family size and national population growth; and that the majority of wives wanted families of from two to four children.

Awards for Medical Writing.—The Editors of *Modern Medical Monographs* announced the 1959 competition for unpublished manuscripts on clinical subjects in the field of internal medicine. The purpose of the awards, known as the Modern Medical Monographs Awards, is "to stimulate young physicians to communicate their work in the classical form of the monograph and to achieve high standards of medical writing." The first prize will be $500. In addition, the authors of manuscripts found suitable will be offered a contract for publication under standard royalty arrangements. The entries will be judged for style and clarity of expression by a committee of the American Medical Writers' Association and for clinical interest and scientific value by the Editors and Advisory Board of *Modern Medical Monographs*. The following rules apply:

1. The author must be a graduate physician, less than 40 years of age.
2. Manuscripts (including illustrations, if any) should be submitted in duplicate (original and one copy) by registered mail, postmarked no later than Oct. 1, to Dr. Richard H. Orr, 33 E. 68th St., New York 21.
3. The manuscript, including the bibliography, must consist of not less than 130, or more than 200, double-spaced typewritten pages with one-inch margins, and not more than 30 illustrations.
4. Dr. Morris Fishbein's book, "Medical Writing" (third edition), should be followed in preparation of the manuscript, use of abbreviations, and bibliographical form.

Orthopedic Convention in Lake Placid.—On June 15-18 the American Orthopaedic Association will hold its 72nd annual session at the Lake Placid Club, Lake Placid, N. Y. Guest of honor will be Dr. Wilfried F. H. M. Mommaerts, professor of medicine and professor of physiology, University of California, Los Angeles, who will present "Fundamental Aspects of Muscle Function." The presidential address will be given by Dr. C. Leslie Mitchell, Detroit. The following papers include the invited authors:

Effects Produced in the Cartilagenous Epiphyseal Plate of Immature Dogs by Experimental Traumata, Drs. Crawford J. Campbell, Andres Grisolia, and George Zanconato, Albany, N. Y.

An Evaluation of Epiphyseodesis and Treatment of Leg Length Discrepancy, Drs. Philip D. Wilson, T. Campbell Thompson, and Lee Ramsay Straub, New York City, and Philip A. Granieri, Boston.

The Effects of Continuous Compression of Articular Cartilage, Dr. R. B. Salter, Toronto, Ontario, Canada.

Fibrous Dysplasia: A Twenty-Five Year Study with Follow-Up, Drs. William H. Harris, Patricia H. Benedict, H. Robert Dudley Jr., and Roy Barry, Boston.

Electromyographic Study of Transplanted Muscles About the Knee in Poliomyelitic Patients, Drs. David H. Sutherland, Frederic C. Bost (deceased), and Edwin R. Schottstaedt, San Francisco.

The Anatomy of Congenital Talipes Equinovarus (with Ten Dissected Specimens), Dr. George W. Settle, Baltimore.

Correlation of the Myelogram to Clinical and Operative Findings in Lumbar Disc Lesions, Drs. Edward Lansche and Lee T. Ford, St. Louis.

The Role of Soft Tissues in Osteogenesis (An Experimental Study of Canine Spine Fusions), Drs. Frank E. Stinchfield, Lloyd A. Hurley, and C. Andrew L. Bassett, New York City.

Discussions will follow each presentation. A program of movies is planned, and entertainment includes the golf tournament and the annual banquet, June 17.

LATIN AMERICA

Colombia Ratifies WHO Constitution.—The Pan American Sanitary Bureau announced that the Republic of Colombia ratified the constitution of the World Health Organization, thereby paving the way for that nation's membership in WHO. Colombia was the only State in the hemisphere which had not ratified the WHO constitution since its drafting in 1946 at the International Health Conference in New York. While Colombia has been a member of the Pan American Health Organization since PAHO's beginnings in 1902, the nation's active participation in WHO will facilitate international measures necessary to protect the peoples of the Americas from disease.

FOREIGN

Convention of Chest Physicians in Israel.—The Israel Association of Chest Physicians is organizing a Convention on Epidemiological Problems of Tuberculosis to take place in Jerusalem, Israel, Sept. 22-23, after the 15th International Tuberculosis Conference in Istanbul. Participants from Europe, the United States, and Asia will read papers. Papers on the experience of Israel with the absorption of immigrants from 70 different countries will also be read. Organized tours of the Holy Land will be included. Applications for registration for attendance should be sent to the Israel Association of Chest Physicians, P. O. Box 8123, Jaffo, Israel.

Hematology Society Meets in London.—The seventh congress of the European Society of Haematology will be held Sept. 7-12 in London under the presidency of Dr. John F. Wilkinson. The principal subjects of the congress will be anemia, leukemia, disorders of coagulation and their treatment, problems of bone marrow transplantation, hemoglobinopathies, new hematological techniques, and the detection and significance of weakly reacting blood group antibodies. The official languages are English, French, and German, and simultaneous interpretation will be arranged by the principal lectures. Scientific films and demonstrations are planned, and the social program will include receptions and a ladies' program. The congress banquet will be held Sept. 10. For information write Dr. E. Neumark, Department of Pathology, St. Mary's Hospital, London, W. 2, England.

CORRECTION

Study of Postgraduate Courses.—In the report of the Council on Medical Education and Hospitals (May 9, pages 206-219) several paragraphs were printed out of their proper sequence. The material beginning with the subhead "The Threshold Factor" on page 214 and ending with the last full paragraph on page 217 which concludes with the words "deny this assumption" should have just preceded the summary.

EXAMINATIONS AND LICENSURE

◆

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Written.* Various locations, July 8, 1960. Final date for filing application is January 8. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Dermatology: *Written.* Several Cities, Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. The final date for filing all applications is July 1, 1959. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *1959 Schedule—Written*, Oct. 19. Final date for filing application was May 1. *Oral.* For candidates on the West Coast, Portland, Ore., Sept. 9-12. Final date for filing application was March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application was March 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Donald D. Matson, 300 Longwood Ave., Boston, Mass.

American Board of Obstetrics and Gynecology: Applications for certificates, new and reopened, Part I, and requests for re-examination Part II are now being accepted. All candidates are urged to make such application at the earliest possible date. Deadline date for receipt of applications is August 1, 1959. No applications can be accepted after that date. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6, Ohio.

American Board of Ophthalmology: *Oral.* Philadelphia, June 2-6; St. Louis, Oct. 6-10. *Written.* January 1960 in various cities. Applications for the 1960 written examination must be filed before July 1. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago. Jan. 19-21, 1960. The deadline for the receipt of application is Aug. 15, 1959. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Final date for filing application was April 1. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: New Orleans, Nov. 12-14. Final date for filing application is October 1. Sec., Dr. Edward B. Smith, Indiana University Medical Center, 1100 W. Michigan St., Indianapolis 7.

American Board of Pathology: *Examination in Forensic Pathology.* New Orleans, Nov. 13. Final date for filing application is October 1. Sec., Dr. Edward B. Smith, Indiana University Medical Center, 1100 W. Michigan St., Indianapolis 7.

American Board of Pediatrics: *Written.* January 1960. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Physical Medicine and Rehabilitation: *Written, Part I,* and *Oral, Part II.* Philadelphia, June 12-13. Final date for filing application was February 15. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Miami, Fla., Oct. 15-17. Final date for submitting case reports is July 1. Corresponding Secretary, Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Proctology: *Oral and Written.* Philadelphia, September. Final date for filing application was March 15. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: Chicago, Oct. 19-20; New York, Dec. 14-15; San Francisco, Mar. 14-15, 1960. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 was terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Examination.* Washington, Dec. 6-9. Deadline for filing application is July 1. Candidates examined in Diagnostic Roentgenology may expect to be examined in Physics. A Special Examination in Nuclear Medicine (for diplomates in Radiology or Therapeutic Radiology) was not given in June 1959. Candidates desiring this examination will be accommodated at the meeting of the Board in Washington, D. C. on December 5. Deadline for filing application is August 1. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Written* examinations (Part I) will be held on December 2, 1959 at various centers to be announced later. Candidates are urged to apply several months before completion of training requirements although the closing date for filing applications is August 1. Those completing training requirements after September 30 cannot be considered for the Part I examination in December of the same year. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, September 1959. Final date for filing application is July 1. *Oral.* September. Final date for filing application is July 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2, Mich.

American Board of Urology: *Written.* Approximately 25 cities throughout the country, December 4, 1959. *Oral-Clinical* and *Examination in Pathology.* Chicago, February 1960. Final date for filing application is Sept. 1, 1959. Sec., Dr. William Niles Wishard, 30 Westwood Rd., Minneapolis 26, Minn.

GOVERNMENT SERVICES

AIR FORCE

Foreign Generals Visit School.—Major Gen. O. K. Niess, the U. S. A. F. surgeon general, and 25 top foreign Air Force surgeons visited the Air Force School of Aviation Medicine at Randolph Air Force Base on April 30. The group made a general orientation tour of selected U. S. government medical service research, clinical, and training facilities. The visiting group included the surgeons general or their representatives from Argentina, Brazil, Canada, Cuba, Chile, Iran, Japan, Mexico, Paraguay, Republic of Korea, Sweden, Switzerland, Taiwan, Thailand, the Philippines, West Germany, and Venezuela.

ARMY

Personal.—Major Gen. James P. Cooney, M.C., has been assigned to Europe as chief surgeon, Headquarters, U. S. Army, Europe, after four years as deputy surgeon general.

Personal.—Col. Harlan H. Taylor, M. C., retired from the Army on March 30 and is now chief surgeon on the passenger liner, President Polk.

NAVY

Personal.—Rear Adm. Lamont Pugh, a former surgeon general of the Navy, has written his autobiography which is entitled, "Navy Surgeon." It is published by J. B. Lippincott Company, of Philadelphia and New York.

VETERANS ADMINISTRATION

Decennial Celebration.—The Veterans Administration Hospital, Houston, Texas, celebrated the decennial of its affiliated operations with Baylor University College of Medicine on April 15. The Administrator of Veterans Affairs, the Hon. Sumner G. Whittier, participated. At a staff dinner, honoring Dr. L. D. Cady, the manager, the Dean's Committee surprised Dr. Cady with an award of merit.

PUBLIC HEALTH SERVICE

Fellowships in Basic Science.—In March, five-year fellowships were awarded to 28 scientists, all of whom have doctoral degrees in medicine, dentistry, or a health-related science. The fellowship program is administered by the Division of General Medical Sciences of the National Institutes of Health. The awards are designed principally for promising young scientists sponsored by university preclinical departments in the period between the completion of their postdoctoral research training and their eligibility for permanent higher academic appointments. Under special circumstances, senior scientists may be awarded these fellowships to supply needed strength in preclinical science departments. The program was started in 1956 with the award of 44 fellowships. The Public Health Service expects to award 40 to 50 new fellowships annually until about 250 have been given. The March awards mark the beginning of the fourth calendar year, with a total of 174 awards made thus far.

The new recipients receiving fellowships are listed in the following table.

State	Recipient	Department	Institution
Alabama	Quigley, Mervyn B.	Anatomy	University of Alabama (Dentistry)
Colorado	Cooper, William G.	Anatomy	University of Colorado
Connecticut	Powell, Wilson F.	Pathology	Yale University
Florida	Schaechter, Moselio	Microbiology	University of Florida
Georgia	Nelson, Leonard	Physiology	Emory University
	Lyon, John B., Jr.	Biochemistry	Emory University
Illinois	Nishimura, Edwin T.	Pathology	Northwestern University
	Combs, C. Murphy	Anatomy	Northwestern University
Louisiana	Geer, Jack C.	Pathology	Louisiana State University
Maryland	Wadkins, Charles L.	Physiology & Chemistry	Johns Hopkins University
Massachusetts	Shuster, Louis	Pharmacology	Tufts University
	Majno, Guido	Pathology	Harvard University
	Padykula, Helen Ann	Anatomy	Harvard University
	Jardetzky, Oleg	Pharmacology	Harvard University
New Hampshire	von Hippel, Peter H.	Biophysics	Dartmouth Medical School
New York	Altszuler, Norman	Pharmacology	New York University
	Lowy, Bertram A.	Biochemistry	Albert Einstein College of Medicine
	Swan, Roy C.	Physiology	Cornell University
	Rogers, Terence A.	Physiology	University of Rochester

North Carolina	Kirshner, Norman	Biochemistry	Duke University
Ohio	Wisotzky, Joel	Pathology	Western Reserve University (Dentistry)
	Green, Gordon E.	Microbiology	Ohio State University (Dentistry)
Pennsylvania	Zilliken, Friedrich W.	Biochemistry	University of Pennsylvania
Tennessee	Grosvenor, Clark E.	Physiology	University of Tennessee
Texas	Critchlow, V. Vaughn	Anatomy	Baylor University
Utah	Eik-Nes, Kristen B. D.	Biology, Chemistry	University of Utah
Washington	Keller, Patricia J.	Biochemistry	University of Washington
Wisconsin	Way, James L.	Pharmacology	University of Wisconsin

Scientists Visit Russia.—Five American scientists, members of a biochemistry delegation, left this country in April for a four-week trip to the Soviet Union to participate in the United States–Russian exchange program. They were Dr. Herbert Carter, Head, Department of Chemistry, University of Illinois, Urbana, Illinois; Dr. Konrad E. Bloch, Professor of Biochemistry, Harvard University, Cambridge, Mass.; Dr. Arthur Kornberg, Professor of Microbiology, Washington University School of Medicine, St. Louis 10; Dr. Albert L. Lehninger, Professor and Chairman, Department of Physiological Chemistry, Johns Hopkins University, Baltimore; and Dr. Bernard D. Davis, Professor of Bacteriology, Harvard Medical School, Boston.

Personal.—Dr. Robert H. Felix, director of the National Institute of Mental Health, was chosen President-elect of the American Psychiatric Association. He will assume the office of president in May, 1960. He served from 1949 to 1958 as chairman of the association's budget committee and was its treasurer in 1958.

FOOD AND DRUG ADMINISTRATION

Pure Food and Drug Violations.—Unfit foods removed from the market during March passed the 1,000-ton mark with the seizure of 61 shipments totaling 1,015 tons. This included 65 tons of frozen eggs made up almost entirely of rotten eggs. Rodent pellet contamination resulted in 16 seizures of bulk wheat and flour, totaling 663 tons. Canned tomatoes, tomato juice, catsup, and tomato puree accounted for 162 of 174 tons of unfit vegetable products seized. Two other seizures stopped 4 tons of dried apples containing insect parts from use by a food processor and 37 tons of canned peaches containing insect parts, fly eggs, and maggots from being served to personnel of the United States Army. Frozen spinach alleged to be adulterated with the pesticide DDT in an amount that may not safely remain in foods without harm to the consumer was seized.

Of 13 drugs and devices seized, 5 were alleged to be misbranded by false and misleading claims. Four were vibrator-massage devices promoted with such claims as weight reduction and relief of nervous tension, cure-all promises, the prevention and cure of serious diseases, even paralysis and heart trouble, and assurance of total health protection and a new way of life. A heat lamp was claimed to benefit sufferers from asthma, arthritis, chest congestion, colds, and hay fever by surrounding them with more healthful air to breathe. A household toilet bowl cleaner did not have the word "Poison" on its label as required by the Federal Caustic Poison Act to help prevent accidental poisonings in the home. Pseudoscience and superstition were the ingredients for promoting a stainless steel wristwatch band as a cure for sciatica, arthritis, bursitis, neuritis, sprains, dislocations, sinusitis, and inflammation. The two Minnesota agents claimed their bracelets contained a tiny generator for converting body heat into "therapeutic" energy. Valued at $3, the bands were being sold for $22.50.

Investigations over several years revealed that Randolph Laboratories, a Division of Randolph Refining Company (a Massachusetts corporation), was actually a one-man firm engaged in repackaging and relabeling multivitamin capsules bought in bulk. Sales and deliveries were conducted by mail to retail dealers. Packaging was carried on in the home basement of a former drug salesman in Wellesley, Mass. The firm shipped products falsely represented to have 2 to 10 times the amounts of vitamins they actually contained and priced to compete with brands put out by reliable firms.

The accused admitted that he had set out deliberately to misrepresent his products for profit because he was in dire financial straits. He said he had been advised this was a good way to make money because no one, including the Food and Drug Administration, checked vitamin products to make sure they contained what they were claimed to have. At sentencing, the judge interrupted the defense plea that consumers had not been injured and said this misrepresentation was an obvious deliberate fraud on consumers and had certainly hurt their pocketbooks, if not their health. The court said that except for the defendant's age and poor state of health he would have been sent to prison. He was fined $1,500.

DEATHS

Atkinson, Donald Taylor Ⓜ San Antonio, Texas; born in Shemogue, New Brunswick, Canada, May 31, 1874; Hospital College of Medicine, Louisville, Ky., 1902; fellow of the International College of Surgeons, American College of Surgeons, and the Royal Academy of Medicine in Ireland; member of the American Academy of Ophthalmology and Otolaryngology, American Association for the Advancement of Science, National Tuberculosis Association, American Genetic Association, American Social Hygiene Association, National Society of Arts and Letters, National Association of Authors and Journalists, and the River Art Group; awarded a medal of merit from the University of Florence for his original researches, as well as a life membership in the National Surgical Society of Italy; associated with Nix Hospital, Santa Rosa Hospital, and Medical and Surgical Hospital; wrote numerous essays and books, including "Great Medical Innovations," "Life Sketches of Great Physicians," "Magic, Myth, and Medicine," and others dealing with his special field of ophthalmology; author of "Texas Surgeon"; received a doctor of science degree from Center College in Danville, Ky., in 1944 and doctor of laws, honoris causa, Huron (S. D.) College in 1945; died in Santa Rosa Hospital March 20, aged 84.

Ausmus, Carl Enlow Ⓜ Jellico, Tenn.; University of Tennessee College of Medicine, Memphis, 1933; died in Clearwater, Fla., March 23, aged 49.

Baker, Bertram Truman, Fort Lauderdale, Fla.; Albany (N. Y.) Medical College, 1912; at one time practiced in Troy, N. Y., where he was on the staff of the Leonard Hospital; died March 31, aged 73.

Barash, David Harry Ⓜ New York City; Long Island College Hospital, Brooklyn, 1911; member of the American College of Cardiology; associated with the New York Polyclinic Medical School and Hospital; died in the Beekman-Downtown Hospital March 19, aged 71.

Bartlett, Mary E., Beloit, Wis.; the Hahnemann Medical College and Hospital, Chicago, 1899; on the staff of the Beloit Hospital; died March 11, aged 89.

Basinger, Adam P. Ⓜ Terrace Park, Ohio; Eclectic Medical Institute, Cincinnati, 1908; practiced in Pleasant Plain and Blanchester; died March 6, aged 77.

Behrendt, Edmund Adelbert Ⓜ Bloomington, Ill.; Northwestern University Medical School, Chicago, 1909; veteran of World War I; on the staff of St. Joseph's Hospital, where he died March 8, aged 76.

Beilby, George Everett Ⓜ Albany, N. Y.; Albany Medical College, 1899; fellow of the American College of Surgeons; served on the faculty of his alma mater; on the staff of the Albany Hospital; died in Pasadena, Calif., March 15, aged 83.

Beisbarth, Carl Conrad Ⓜ St. Louis; St. Louis University School of Medicine, 1926; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology; assistant clinical professor of ophthalmology at Washington University School of Medicine; associated with the Barnes, DePaul, St. Louis City, and McMillan hospitals; died March 13, aged 57.

Bennett, Thomas Wade Ⓜ Captain, U. S. Navy, retired, La Jolla, Calif.; University of Nebraska College of Medicine, Omaha, 1925; fellow of the American College of Physicians; member of the American Society of Clinical Pathologists; veteran of World Wars I and II; retired from the U. S. Navy Aug. 1, 1953; died March 17, aged 60.

Bergen, Frank Leslie Ⓜ Burlington, Colo.; Denver and Gross College of Medicine, 1908; died Feb. 25, aged 81.

Bernard, Romeo Armand, Lewiston, Maine; Tufts College Medical School, Boston, 1926; on the staff of St. Mary's General Hospital; died March 3, aged 61.

Blake, Thomas Wallace Ⓜ Seattle; Johns Hopkins University School of Medicine, Baltimore, 1927; specialist certified by the American Board of Radiology; certified by the National Board of Medical Examiners; member of the Radiological Society of North America; veteran of World War I; member of the staff of the Swedish Hospital, where he died March 28, aged 60.

Blick, William, Crafton, Pa.; University of Pittsburgh School of Medicine, 1910; died in St. Margaret Memorial Hospital, Pittsburgh, March 20, aged 77.

Bloomer, Joseph R. Ⓜ Rockville, Ind.; the Hahnemann Medical College and Hospital, Chicago, 1907; member of the American Academy of General Practice; died March 21, aged 77.

Blumgart, Leonard Ⓜ New York City; Columbia University College of Physicians and Surgeons, New York City, 1903; veteran of World War I; past-presi-

---

Ⓜ Indicates Member of the American Medical Association.

dent of the New York Psychoanalytic Society; member of the American Psychoanalytic Association and the American Psychosomatic Society; from 1938 to 1950 instructor at the New York Psychoanalytic Institute; served as an associate attending psychoanalyst at the psychoanalytic clinic for training and research of Columbia University; formerly on the board of visitors of Westfield State Farm in Bedford Hills, N. Y.; died March 20, aged 78.

Boyce, Lee Ⓜ San Marcos, Calif.; Jefferson Medical College of Philadelphia, 1903; veteran of the Spanish-American War; formerly practiced in Philadelphia; while in Los Angeles, was affiliated with the French Hospital and the Queen of Angels Hospital; died in San Diego March 12, aged 78.

Brandenburg, Kenneth Charles Ⓜ Long Beach, Calif.; University of Illinois College of Medicine, Chicago, 1926; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology; past-president and secretary of the Harbor Branch of the Los Angeles County Medical Association; served as a director of the Long Beach Tuberculosis and Health Association; a member of the staffs of Seaside, St. Mary's, and Community hospitals; past-president of the Mental Hygiene Clinic; served as president of the Lions Club; died March 10, aged 59.

Brant, Cornelia Chase, Bronxville, N. Y.; New York Medical College and Hospital for Women, Homeopathic, New York City, 1903; served as dean of her alma mater; during World War I organized a women's base hospital unit for service in France; associated with the Cumberland Street Hospital in Brooklyn; died March 9, aged 95.

Brawner, James N. Ⓜ Smyrna, Ga.; College of Physicians and Surgeons, Baltimore, 1899; member of the House of Delegates of the American Medical Association in 1923; member of the American Psychiatric Association; past-president of the Fulton County Medical Society; served as medical director of Brawner's Sanitarium, of which he was founder; died March 7, aged 82.

Brown, Oscar Vineyard Ⓜ Island, Ky.; Kentucky University Medical Department, Louisville, 1904; past-president of the McLean County Medical Society; served as a representative in the state legislature and later as state senator; in 1946 became health officer for McLean County, and four years later was health officer for Ohio County, continuing in both offices until his retirement; for many years president of Island Deposit Bank and of the Island Mercantile Company; died in the Owensboro-Daviess County Hospital in Owensboro March 13, aged 84.

Bryan, Samuel Ⓜ Memphis, Tenn.; Harvard Medical School, Boston, 1926; member of the American Academy of General Practice; died March 16, aged 57.

Bubert, John Diederick Ⓜ Baltimore; Baltimore Medical College, 1912; member of the American Academy of General Practice; founding member of the Maryland Academy of General Practice; served on the staffs of the Church Home and Hospital, Maryland General Hospital, and the University Hospital; died in the Union Memorial Hospital March 19, aged 72.

Burke, Rush Pearson Ⓜ Montgomery, Ala.; Columbia University College of Physicians and Surgeons, New York City, 1908; veteran of World War I; died March 19, aged. 74.

Burns, Harry John, Duluth, Minn.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1903; veteran of World War I; formerly associated with the Indian Service; served on the staffs of the St. Mary's and St. Luke's hospitals; died in St. Mary's Hospital March 13, aged 77.

Byrne, William Roger Ⓜ Holliston, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1916; served in France during World War I; for many years chairman of the board of health; on the staff of the Framingham (Mass.) Union Hospital, where he died March 7, aged 66.

Calvert, Edward Harrison Ⓜ El Cajon, Calif.; Ohio State University College of Medicine, Columbus, 1927; on the staff of the Vista Hill Psychiatric Foundation in Chula Vista; formerly on the staffs of the Mendocino State Hospital, Talmage, and the Atascadero State Hospital in Atascadero; served as consulting psychiatrist for the Department of Correction, State of California; died March 19, aged 70.

Cameron, Prince Wendell, Chicago; Illinois Medical College, Chicago, 1911; died March 24, aged 80.

Carter, Robert Elsworth Ⓜ Jamaica, N. Y.; University and Bellevue Hospital Medical College, New York City, 1927; fellow of the American College of Surgeons; veteran of World War II; specialist certified by the American Board of Surgery; director and founder of the Allied Federal Savings and Loan Association of Jamaica; associated with the Harlem and Doctors hospitals in New York City and the Memorial Hospital; died March 17, aged 58.

Cunningham, Jacob Metz Ⓜ Philadelphia; Jefferson Medical College of Philadelphia, 1912; on the staff of the Chestnut Hill Hospital; died March 14, aged 74.

Digges, Francis Harry, Prince Frederick, Md.; University of Maryland School of Medicine, Baltimore, 1904; retired surgeon, Baltimore and Ohio Railroad; died in the Calvert County Hospital March 3, aged 82.

Dight, Herman Herschel Ⓜ Altoona, Pa.; Jefferson Medical College of Philadelphia, 1901; served as president of the Blair County Medical Society; past-president of the Western Pennsylvania Eye, Ear, Nose and Throat Society; served on the staff of the Wills Eye Hospital in Philadelphia; on the staff of Altoona Hospital; for many years on the staff of the Mercy Hospital; died in the Jefferson Hospital, Philadelphia, March 13, aged 79.

Dodge, Albert Arthur Ⓜ Kalispell, Mont.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1894; past-president of the Flathead County Medical Society; for many years county health officer; for many years on the board of the Kalispell Hospital; died March 3, aged 91.

Dupertuis, S. Milton Ⓜ Pittsburgh; born in Tacoma, Wash., Jan. 31, 1906; Harvard Medical School, Boston, 1932; associate professor of plastic surgery at the University of Pittsburgh School of Medicine; certified by the National Board of Medical Examiners; specialist certified by the American Board of Surgery and the American Board of Plastic Surgery, of which he was chairman; member and past-president of the American Society of Plastic and Reconstructive Surgery; member of the American Association of Plastic Surgeons and the American Society for Surgery of the Hand; fellow of the American College of Surgeons; resigned from the U. S. Public Health Service Jan. 31, 1938; veteran of World War II; president of the staffs of Presbyterian and Woman's hospitals; associated with Eye and Ear Hospital, St. Margaret Memorial Hospital, Children's Hospital, Veterans Administration Hospital, and the Western Pennsylvania Hospital; associate editor, *Journal of Plastic and Reconstructive Surgery;* died March 26, aged 53.

Eagles, Charles Sidney, Saratoga, N. C.; University of North Carolina School of Medicine, Chapel Hill, 1909; died March 5, aged 77.

Eckstein, Joseph Goossen, Cincinnati; Medical College of Ohio, Cincinnati, 1900; veteran of World War I; died March 11, aged 86.

Eggleston, Harry Robert Ⓜ Grand Rapids, Mich.; Detroit College of Medicine and Surgery, 1928; on the staff of St. Mary's Hospital; died March 3, aged 58.

Ervin, John Herbert, Jenkintown, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1903; member of the staff of the Abington (Pa.) Memorial Hospital; died March 11, aged 79.

Fettig, Carl Alexander Ⓜ Grosse Pointe Park, Mich.; Detroit College of Medicine, 1899; associated with the William Booth Memorial Hospital and the Grace Hospital, Detroit, where he died March 3, aged 82.

Frey, Clarence Wilson Ⓜ Millerstown, Pa.; University of Pittsburgh School of Medicine, 1913; county coroner; member of the Pennsylvania State Coroners' Association; veteran of World War I; at one time practiced in Dallastown, where he was president of the bank; served as president and secretary of the staff of the York (Pa.) Hospital; died March 18, aged 66.

Gallagher, James Leo Ⓜ Buffalo; Baltimore Medical College, 1902; veteran of World War I; associated with the Emergency Hospital and Sisters of Charity Hospital, where he died March 10, aged 81.

Gallimore, Robert Geary Ⓜ Milwaukee; Creighton University School of Medicine, Omaha, 1943; veteran of World War II; died March 2, aged 41.

Gamble, John Ellison, Steubenville, Ohio; Ohio State University College of Medicine, Columbus, 1920; on the staffs of the Ohio Valley and Gill Memorial hospitals; died March 12, aged 67.

Gay, Andrew Jackson Ⓜ Long Beach, Miss.; Chicago College of Medicine and Surgery, 1913; member of the Southeastern Surgical Congress and the American Academy of General Practice; died in Ochsner Foundation Hospital, New Orleans, March 12, aged 70.

Gibby, Harold James Ⓜ Worcester, Mass.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; specialist certified by the American Board of Otolaryngology; on the staff of the Memorial Hospital; died March 2, aged 76.

Gillette, Arthur Edwin, Cincinnati; Medical College of Ohio, Cincinnati, 1893; died March 16, aged 89.

Gilmore, Clifford Freeman Ⓜ Falls Church, Va.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; died March 2, aged 87.

Grimm, Emery Gabriel Ⓜ Chicago; Medizinische Fakultät der Universität, Vienna, Austria, 1921; associate in the department of medicine, Northwestern University Medical School; on the staff of the Wesley Memorial Hospital; at one time practiced in Milwaukee, where he was associated with the Sacred Heart Sanitarium and St. Joseph's Convent; died in the Albert Merritt Billings Hospital March 19, aged 64.

Haines, Dempsey D. Ⓜ Charleroi, Pa.; Western University of Pennsylvania Medical Department, Pittsburgh, 1903; associated with the Charleroi–Monessen Hospital, where he died March 15, aged 94.

Harmon, Clair G. Ⓜ Easton, Pa.; Kentucky University Medical Department, Louisville, 1906; served on the staff of the Easton (Pa.) Hospital; died in the Holy Cross Hospital, Fort Lauderdale, Fla., March 8, aged 76.

Harz, John George Ⓜ New Orleans, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1904; also a pharmacist; died March 3, aged 82.

Heise, Carl August, Story City, Iowa; Rush Medical College, Chicago, 1906; died in Ottawa, Kan., March 22, aged 78.

Herff, John Bennett, San Antonio, Texas; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; died March 11, aged 80.

Herzog, George Kramer Ⓜ San Francisco; Cooper Medical College, San Francisco, 1901; veteran of World War I; associated with Polyclinic Hospital, Children's Hospital, and the Mount Zion Hospital, where he died March 16, aged 80.

Horn, Clinton, San Mateo, Calif.; Bennett Medical College, Chicago, 1915; served on the staff of the Southern Pacific Hospital in San Francisco, where he died March 6, aged 74.

Howlett, Edward Vernard Ⓜ Pontiac, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; fellow of the American College of Surgeons; past-president of the Oakland County Medical Society; chief of staff of Pontiac General Hospital medical staff; died March 12, aged 83.

Hubbard, John Clarence, Oklahoma City, Okla.; Eclectic Medical University, Kansas City, Mo., 1918; chairman of the city-county health board; veteran of World War II; founder, administrator, and consultant of Hubbard Hospital, where he died March 18, aged 74.

Hunt, Kent Noel Ⓜ San Antonio, Texas; University of Texas School of Medicine, Galveston, 1929; veteran of World War II; associated with Nix, Santa Rosa, and Baptist Memorial hospitals; died March 11, aged 56.

Inge, Claude William Ⓜ Concordia, Kan.; Barnes Medical College, St. Louis, 1911; for three years secretary of the Franklin (Tenn.) Medical Society; assistant examiner, Selective Service, Franklin County, Mo., during World War I, and chief examiner, Jewell County, Kan., during World War II; medical director, Farm Security Administration, Jewell County; board member, Kansas Blue Shield; local surgeon, Chicago, Rock Island & Pacific Railway; staff member, St. Joseph's Hospital; died March 2, aged 75.

Jackson, Leland Forney Jr., Baird, Texas; Baylor University College of Medicine, Dallas, 1943; veteran of World War II; interned at the Buffalo General Hospital, where he served a residency; served a residency at the Baylor University Hospital and the Parkland Hospital in Dallas; on the staff of Callahan County Hospital; died in the Harris Hospital, Fort Worth, March 1, aged 41.

Jackson, Thomas Grant Ⓜ Gorman, Texas; Memphis (Tenn.) Hospital Medical College, 1910; served on the staff of the Blackwell Hospital, where he died March 19, aged 76.

Johnson, Lewis David Ⓜ Kansas City, Mo.; Denver College of Medicine, 1899; medical director of the Johnson Hospital in Chanute, Kan., which he owned; died in Santa Ana, Calif., March 2, aged 81.

Juckem, George Joseph Ⓜ Sheboygan, Wis.; Marquette University School of Medicine, Milwaukee, 1915; veteran of World War I; past-president of the Sheboygan Lions Club; past-president of the North Side Bank; died March 8, aged 67.

Kaulbach, Joseph I., Spokane, Wash.; Dartmouth Medical School, Hanover, N. H., 1891; from 1929 to 1940 a Montana state senator from Choteau County; died March 16, aged 96.

Keiser, Forrest Le Grand Ⓜ Columbus, Ohio; Ohio Medical University, Columbus, 1907; served as assistant superintendent and superintendent of the Columbus State School; died March 7, aged 79.

Kelly, Paul Edward Ⓜ Chicago; Northwestern University Medical School, Chicago, 1908; on the staff of the Ravenswood Hospital, where he died March 28, aged 77.

Klein, Abraham Arthur, Hartford, Conn.; University of Louisville (Ky.) School of Medicine, 1929; served as school physician and police surgeon; on the staffs of Mount Sinai and St. Francis Hospitals; died March 3, aged 58.

Knox, Barron Dwinell Ⓜ Springfield, Mass.; Tufts College Medical School, Boston, 1937; specialist certified by the American Board of Urology; member of the American Urological Association; veteran of World War II; consultant, Mary Lane Hospital in Ware, Cooley Dickinson Hospital, Northampton, and the Wesson Memorial Hospital; chief urologist, Noble Hospital, Westfield, Wing Memorial Hospital in Palmer, and the Springfield Hospital; died March 12, aged 47.

Kramer, Abraham Ⓜ Philadelphia; Hahnemann Medical College and Hospital, Philadelphia, 1934; also a graduate in pharmacy; veteran of World War II; died in the Hahnemann Hospital March 27, aged 57.

Lambright, Middleton Hughes, Cleveland; Meharry Medical College, Nashville, Tenn.; 1898; practiced in Kansas City, Mo.; one of the founders, and honorary member of the Forest City Hospital medical staff; died March 21, aged 94.

La Motte, George Althonse Ⓜ Oklahoma City, Okla.; Jefferson Medical College of Philadelphia, 1901; died in the Belleview Hospital March 1, aged 82.

Lowy, Moriz Ⓢ New York City; Medizinische Fakultät der Universität, Vienna, Austria, 1915; associated with the Sydenham Hospital; died March 19, aged 68.

McAlister, Gordon, Highland Park, Mich.; Detroit College of Medicine, 1897; on the staff of the Highland Park General Hospital, where he died March 14, aged 86.

McCleave, Thomas Crooke Ⓢ Berkeley, Calif.; Cooper Medical College, San Francisco, 1896; member of the House of Delegates of the American Medical Association in 1915 and chairman, Section on Diseases of Children, 1915-1916; member of the American Academy of Pediatrics; fellow of the American College of Physicians; veteran of the Spanish-American War and World War I; served as president of the Alameda County Milk Commission and on the council of the American Milk Commission; died March 11, aged 86.

McCrary, John Donald Ⓢ Manhattan, Kan.; University of Nebraska College of Medicine, Omaha, 1950; interned at University of Texas Medical Branch Hospitals, Galveston; served a residency at the University Hospital in Cleveland and the University of Nebraska Hospital in Omaha; for two years served in the medical reserve corps of the U. S. Army; died in Marion, March 6, aged 32.

McGuire, Thomas Edward Ⓢ Glendale, Calif.; Maryland Medical College, Baltimore, 1904; died in the Good Samaritan Hospital, Los Angeles, March 16, aged 77.

McQuarrie, John Gray Ⓢ Richfield, Utah; University of California School of Medicine, San Francisco, 1919; member of the American Academy of General Practice; twice president of the Sevier County Medical Society; past-honorary-president of the Utah Medical Association; during World War II was a member of the Sevier County Selective Service board and received a medal for his services; on the staff of the Sevier Valley Hospital; died March 1, aged 69.

Mabry, Irving Ellis, Bridgton, Maine; Medical School of Maine, Portland, 1909; on the staff of the Northern Cumberland Memorial Hospital; died March 4, aged 80.

Malgeri, John, Newark, N. J.; L.R.C.P., Edinburgh, L.R.C.S., Edinburgh, and L.R.F.P.&S., of Glasgow, Scotland, 1938; veteran of World War II; died in St. Michael's Hospital March 22, aged 51.

Martin, Donald David, Rockford, Ill.; St. Louis University School of Medicine, St. Louis, 1920; served on the staff of St. Anthony Hospital, where he died March 11, aged 66.

Mason, Wilford John, Los Angeles; University of Illinois College of Medicine, Chicago, 1931; veteran of World War II; died March 6, aged 60.

Melton, Andy Singleton Ⓢ Okemah, Okla.; University of Arkansas School of Medicine, Little Rock, 1912; president of the Okfuskee County Medical Society; on the staff of Okfuskee County Hospital; died March 1, aged 73.

O'Connor, Christopher Sebastian, Plattsburg, Mo.; St. Louis University School of Medicine, 1907; died March 7, aged 83.

Olson, Charles August Ⓢ St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1911; on the staff of the Bethesda Hospital; died March 17, aged 71.

Osborne, Ernest Sumner Ⓢ West Dennis, Mass.; Tufts College Medical School, Boston, 1902; a charter staff member of the Cape Cod Hospital in Hyannis; died March 2, aged 83.

Penrod, Lucian, Taft, Texas; Baylor University College of Medicine, Dallas, 1908; veteran of World War I; died in Sinton March 9, aged 73.

Reeder, Thomas Pickens Jr. Ⓢ Newport Beach, Calif.; University of Texas School of Medicine, Galveston, 1936; interned at Jefferson Davis Hospital in Houston, Texas; served a residency at Los Angeles County Hospital in Los Angeles; veteran of World War II; died Feb. 26, aged 47.

Richardson, James Joseph Ⓢ Fort Worth, Texas; St. Louis University School of Medicine, 1912; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; associated with the W. I. Cook Memorial Hospital Center for Children, St. Joseph's Hospital, and the Harris Hospital, where he died March 7, aged 78.

Robinson, William Click Ⓢ Lexington, Ky.; Tulane University School of Medicine, New Orleans, 1942; veteran of World War II; at one time fellow in surgery at Mayo Foundation in Rochester, Minn.; died March 7, aged 41.

Rollings, John Adolph, Richmond, Va.; George Washington University School of Medicine, Washington, D. C., 1912; served in France during World War I; vice-president and director of the Grace Hospital; associated with the Retreat for the Sick; died March 10, aged 69.

Rosenhain, Erich Ⓢ Jackson Heights, N. Y.; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1912; died in the Doctors Hospital, New York City, March 3, aged 70.

Rotkin, Meyer M. Ⓢ New York City; New York Homeopathic Medical College and Flower Hospital, New York City, 1916; died March 8, aged 73.

Sample, James Lindsey Ⓢ Hampton, S. C.; University of Georgia Medical Department, Augusta, 1914; died in the Talmadge Memorial Hospital, Augusta, March 5, aged 70.

Sands, Kenneth Fillman, Milton, Mass.; Johns Hopkins University School of Medicine, Baltimore, 1943; veteran of World War II; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; school physician; instructor in pediatrics at Harvard Medical School in Boston, where he was associated with the Children's Medical Center and the Boston Lying-in Hospital; on the staff of the Milton Hospital and Convalescent Home, where he died March 11, aged 41.

Shaffer, Claude, Houston, Texas; (licensed in Texas, by the years of practice); died in Bryan March 10, aged 93.

Sheehy, Martin James Ⓜ Ridgewood, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1928; served on staff of the Wyckoff Heights Hospital in Brooklyn, where he died March 2, aged 54.

Somerville, John Wilson, Atlanta, Ga.; University of Virginia Department of Medicine, Charlottesville, 1904; veteran of World War I; served in the regular U. S. Army; died March 6, aged 77.

Southard, Harry Green Ⓜ Marysville, Ohio; Starling Medical College, Columbus, 1906; past-president of the Union County Historical Society; served two terms on Marysville Council and was a president of the Marysville Board of Education; formerly state director of health and health commissioner for Hocking, Vinton, and Athens counties; at one time health director of Union County; died Feb. 16, aged 81.

Swafford, Jesse Brown Ⓜ Chattanooga, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1915; past-president of the Chattanooga-Hamilton County Medical Society; superintendent of the William L. Bork Memorial Hospital; died March 8, aged 67.

Swan, Horace Cheney Ⓜ Hartford, Conn.; Tufts College Medical School, Boston, 1903; fellow of the American Association for the Advancement of Science and the American Public Health Association; professor emeritus and medical director emeritus of Trinity College; during World War I commandant of American Red Cross Sanitary Unit No. 2 and also served as a contract surgeon for the Army; died March 1, aged 80.

Thomas, Hall H., Denver; Rush Medical College, Chicago, 1906; veteran of World War I; died in February, aged 81.

Wachtel, Jacob Ⓜ New York City; Fordham University School of Medicine, New York City, 1921; specialist certified by the American Board of Dermatology and Syphilology; assistant clinical professor of dermatology and syphilology at the New York College of Medicine; on the staffs of the Jewish Memorial Hospital, Goldwater Memorial Hospital, and the University Hospital (New York University-Bellevue Medical Center); died in the Jewish Memorial Hospital March 11, aged 61.

Wallace, Hamilton Cornwallace, Pottsville, Pa.; Medico-Chirurgical College of Philadelphia, 1906; past-president of the board of health; veteran of World War I; served on the staff of the Pottsville Hospital; for many years physician and surgeon for the Philadelphia and Reading Coal and Iron Company and was medical examiner for the Reading Railroad; died Feb. 9, aged 76.

Wallace, Virgle Wesley Ⓜ Odessa, Texas; University of Oklahoma School of Medicine, Oklahoma City, 1943; interned at the University Hospitals in Oklahoma City, where he served a residency; served a residency at St. Anthony Hospital in Oklahoma City and St. Luke's Hospital in Kansas City, Mo.; fellow of the American College of Surgeons; died Jan. 7, aged 49.

Wardle, Henry Ⓜ St. Petersburg, Fla.; Jefferson Medical College of Philadelphia, 1907; past-president of the South Bristol District of the Massachusetts Medical Society; for many years medical examiner for the Metropolitan Life Insurance Company; formerly practiced in Fall River, Mass., where he was associated with the Union and St. Anne's hospitals; during World War II medical examiner for the Draft Board; died in the Mound Park Hospital March 2, aged 74.

Warner, James Gamble Ⓜ Pittsburgh; University of Wooster Medical Department, Cleveland, 1907; veteran of World War I; for many years practiced in Cleveland, where he was associated with Woman's and St. Luke's hospitals, and member of the Cleveland Medical Library Association; died Feb. 24, aged 75.

Waste, John Morton, Glendale, Calif.; College of Physicians and Surgeons of San Francisco, 1918; for 25 years medical examiner for Equitable Life Insurance Company; died in the Memorial Hospital Feb. 2, aged 79.

Watt, Archibald Henderson Ⓜ New York City; University of Michigan Medical School, Ann Arbor, 1918; on the staffs of the Morrisania and Fitch hospitals, and the Union Hospital, where he died Feb. 23, aged 66.

Wilson, Redford Alexander Ⓜ Tucson, Ariz.; Vanderbilt University School of Medicine, Nashville, Tenn., 1926; member of the American College of Chest Physicians and the American Trudeau Society; fellow of the American College of Physicians; affiliated with St. Mary's Hospital and Tucson Medical Center; died Feb. 13, aged 58.

FOREIGN LETTERS

AUSTRIA

Medical Education.—At a meeting of the Society of Physicians in Vienna the questions of whether there was a shortage of physicians and whether the study of medicine should be encouraged were discussed. For years Austria has been one of the countries with a larger than average number of physicians per unit population—one physician for 563 inhabitants in 1955, as compared to one for 1,692 inhabitants in 1890. This development is responsible for the fact that physicians now have great difficulty getting enough practice to make a living. Until 1957 there was such an excess of physicians in training in hospitals that hospital managers paid only a pittance to the employed physicians. For this reason hospitals, especially in rural areas, have noted a decrease in applicants for jobs as hospital physicians. Some hospitals are now unable to find such applicants. This relative shortage of physicians on one side is in contrast to the large number of physicians who have terminated their schooling and would like to enter private practice. They are prompted to do so because of their desire to make a living for a family of their own and to acquire a home of their own. Service quarters in a hospital are not sufficient in the long run to satisfy these normal desires.

It is not easy for any physician to establish a practice during the first years. This is even more difficult in the overcrowded rural districts and the capitals of the federal states. Without a contract with the state medical insurance funds it is hardly possible for a physician to make a living. In Vienna alone 507 physicians who have opened private offices are waiting for appointments with the insurance funds. This is also the reason for the emigration of about 50 Austrian physicians to Sweden in 1958. It would thus be a serious error to assume that there is a genuine shortage of physicians in Austria, and that, consequently, students should be encouraged to take up the study of medicine. High school students are again and again given misguided advice concerning the medical profession because of unawareness of the true situation on the side of the consultants.

The Austrian chamber of physicians, however, has no intention of cautioning students against the study of medicine, but it does emphasize that an inordinate number of young physicians are working in the university clinics. These clinics are already overcrowded with students and it is becoming increasingly difficult to give the necessary training. The apparent shortage of physicians in rural hospitals is due to uneven distribution.

BELGIUM

Tuberculosis in the Congo.—At the Phthisiology Congress in Brussels in 1958, Kivits stated that in the Belgian Congo tuberculosis was originally a disease of the urban centers but that little by little the disease had appeared in rural areas, being brought there by sick workers leaving their jobs to return to their native villages. Skin tests showed that tuberculosis has reached even the most remote areas. Radiologic examinations showed that the average morbidity in the Belgian Congo was 0.8%. The antituberculosis fight will be effective only if it is based on a general program of improvement of social and economic conditions which influence the diet, housing, and sanitary education of the population. At present the diet is grossly deficient in proteins and the dwellings are particularly unhygienic.

As a result of geographical, social, and economic difficulties it is impossible to construct a sufficient number of sanatoriums. This is why the government has constructed tuberculosis annexes to the general hospitals. The sanatoriums, directed by phthisiologists, remain the pilot organizations of the antituberculosis campaign. Ordinarily, on conversion of the sputum and radiologic stabilization of the lesions, it is necessary to rely on ambulant treatment, especially in the urban centers where the patient is carefully watched. The average period of hospitalization is three months in the cities and one year in the rural areas. In the latter cases patients on the way to stabilization are usually placed in convalescent camps. BCG vaccination does not eliminate the importance of using all other available control measures.

Progress in Tuberculosis Control.—At the same meeting it was pointed out that in general the nutrition of the population has improved in the last 25 years. In 1936 shortages of milk, cheese, vegetables, butter, and fruits and therefore of calcium, vitamin A, and vitamin B_2 were noted. Now the nutrition of the population is not so much a question of budget as of information. The most frequently noted deficiencies can easily be compensated by the daily addition of one-half liter of milk. The pre-employment medical examination of

all persons under 21 and the annual physical checkup employed persons in this age group must undergo have also helped to reduce the incidence of tuberculosis in adolescents. From 1948 to 1955 the incidence of tuberculosis among adolescents at work fell from 1.55 to 0.23%.

The death rate from tuberculosis has decreased markedly in the last 25 years. The pronounced drop which characterized the immediate postwar period has tended to level off. The difference in death rates for the two sexes was again accentuated. In 1930 there were 87 women for every 100 men dying of tuberculosis; in 1945 there were 56; and in 1956, there were 29. Rates in women have regressed even in the oldest groups, and among women aged 45 and over there has been no notable increase since 1935.

Tinnitus Aurium.—Hicguet and Van Eyck (*Acta Otorhinolaryngologica de Belgique*) differentiated objective and subjective forms of tinnitus aurium. The former results from the transmission to the ear of vascular somatic sounds. The associated deafness is not due to an auricular lesion but results from the masking effect of these sounds. Subjective tinnitus is provoked by an alteration of the auditory structure, and it is always accompanied by true deafness. It can be caused by an obstacle located in the external auditory canal (cerumen, exostoses, or foreign body) or in the middle ear (scar lesions or ankylosis of the ossicles). The most intense subjective tinnitus is due to lesions in or near the auditory nerve, as in patients with aural vertigo, presbyacusia, and tumors of the ear. The factor responsible for abnormal auditory stimulation is usually a disturbance of the autonomic nervous system which produces a vasomotor disorder. It may be reflex in patients with cervical arthrosis or sinusitis; dyscrasic in patients with uremia, hyperglycemia, or cholesteremia; or psychosomatic.

BRAZIL

Nuclear Medicine Center.—On Jan. 25 the Center of Nuclear Medicine of the University of São Paulo was opened. This building centralizes all the medical and biological applications of radioactive isotopes. The basement contains facilities for handling isotopes up to a level of several curies, with a junior cave, master-slave manipulators, and additional space for preparing isotopes for clinical and research uses. This permits the importation of isotopes in large shipments, making them much cheaper. The prepared isotopes are distributed to other floors by a dumb-waiter. The basement also contains decay tanks, an incinerator, a well for radioactive ashes, and general utilities stations. The ground floor includes rooms for examination of patients and isotope diagnosis, several laboratories, and a separate room for the application of therapeutic doses of radioactive substances. There are also two bedrooms where patients are kept while they still constitute a radiation hazard. Auxiliary facilities such as offices, waiting rooms, and coat rooms are included.

The second floor contains a lecture room, student laboratories, auxiliary rooms for teaching, and a library. The third floor is given over to biological research. It contains two radiochemistry laboratories; two counting rooms; a normal chemistry laboratory; several rooms for physics, mechanics, and electronics; a nuclear magnetic resonance–mass spectrometer; and auxiliary facilities for basic research. The fourth floor is only partially used and contains animal quarters, a greenhouse for growing radioactive plants, and the necessary auxiliary services. The concentration of all types of application of isotopes in a single building offers great advantages regarding the best uses of equipment, technical personnel, and isotopes.

DENMARK

Heparin and Tinnitus.—Kaj Zilstorff-Pedersen (*Nord. med.* 61:223-224 [Feb. 5] 1959) reported treating a series of 52 patients who had subjective tinnitus by administering 5,000 international units of heparin intravenously daily for six days. Seventeen of the patients were cured or much improved. In 3 to 10 weeks tinnitus recurred in most patients, but a few injections of heparin again relieved the symptoms. The hearing also became subjectively better in 17 patients, although not always in the same ones in which tinnitus was improved. The subjective improvements in hearing could not be demonstrated objectively.

Phenylbutazone in Ophthalmology.—Poul Svane-Knudsen (*Nord. med.* 61:226-228 [Feb. 5] 1959) used phenylbutazone to treat seven patients with iritis, iridocyclitis, and chronic uveitis, one with diskiform keratitis, and seven with scleritis and episcleritis. In all these patients there was a prompt and powerful analgesic effect and a rapid clearing of hyperemia and exudation in the anterior ocular chambers. A patient with choroiditis did not respond to the treatment. The special indications were (1) postoperative and post-traumatic irritations, (2) tuberculosis or suspected tuberculosis, (3) pituitary basophilism, (4) previous treatment with cortisone, and (5) diabetes with oscillations in the blood sugar level. The drug should be used with caution because of its side-effects.

Pheochromocytoma.—E. Dahl-Iversen (*Acta chir. scandinav.* 116:118-131, 1958/1959) studied 18 patients with pheochromocytomas. In the 15 patients from whom the tumor was removed 14 tumors were intra-adrenal and 1 was ectopic. Among these patients there were no deaths, but the remaining three patients were in such poor condition that they died before the tumor could be localized. Of the 18 patients 3 showed signs of renal failure resembling lower nephron nephrosis. After removal of the tumor and stabilization of the blood pressure 11 of 14 patients had a normal blood pressure whereas three had blood pressures of 150/95 to 160/100 mm. Hg. On reexamination of the 15 patients operated on, after six months to 12 years (average 4.3 years), normal blood pressure was found in 13 and in 2 the blood pressures were 180/130 and 230/150 mm. Hg.

Primary Varicose Veins.—The deep veins of the leg were studied phlebographically by the tilting technique in 275 patients with primary varicose veins by F. R. Mathiesen (*Acta chir. scandinav.* 116:155-162, 1958/1959). In the interpretation of the phlebograms the series was divided according to the following criteria: (1) spindle-shaped dilatation of the veins of the lower leg, (2) filling of the larger muscular veins, (3) filling of fine muscular collaterals, and (4) functional capacity of the deep veins of the leg. Patients with recurrent varicose veins after previous operation showed greater incompetence of the valves of the deep veins, whereas venous dilation seemed to be without importance in the development of varicose veins or accompanying discomforts.

Filling of the large muscular veins might be related to an increased tendency to discomforts and seemed to occur slightly more frequently in patients with recurrent varicose veins after previous treatment, but the study did not allow any definite conclusions on this point. On the other hand it was observed that fine muscular collaterals occurred almost exclusively in patients with varicose veins, in particular in patients who had previously been treated with operation or injection, and that the discomforts seemed to be more frequent and more severe among patients in whom phlebography revealed filling of fine muscular collaterals. On the basis of the investigation it could not be decided whether the frequent occurrence of fine muscular collaterals was evidence of selection because of a special tendency to discomfort in these patients or a sign of venous damage referable to previous operation.

Supracondylar Fractures of the Humerus.—A series of 58 children aged from 6 months to 14 years were treated for supracondylar fracture of the humerus by Frede Bro-Rasmussen and co-workers (*Acta chir. scandinav.* 116:134-143, 1958/1959). Of these 37 fractures involved the left arm. The fractures were reduced by means of the Persson frame in seven and manual reduction was used in the rest. The arm was immobilized with the elbow in about 90-degree flexion and varying degrees of pronation. Thoracobrachial plaster casts were used on 14 patients and various modifications of circular plaster casts on the rest. The duration of immobilization was 3 to 13 weeks (average 6 weeks). Immobilization was recommended for three to six weeks, depending on the severity of the fracture, followed by active exercises to just below the threshold of pain. Irrespective of the principle of treatment used good function usually resulted after supracondylar fractures of the humerus, even though satisfactory reduction might not have been accomplished. Anatomic and cosmetic deformities improved with time.

Increasing cubitus varus deformity due to unequal epiphysial growth was not observed, nor did late ulnar nerve symptoms occur after fractures healed in the valgus position. The physiological importance of the valgus position, which was often pronounced during childhood, was emphasized. Failure to recognize this might be the cause of the occurrence of cubitus varus deformity. The simplest and gentlest method of reduction that gives satisfactory results should be preferred. A method that fulfills these requirements is to place the patient in the prone position with the arm in 90-degree abduction, to exert manual traction on the forearm, with flexion of the elbow joint across the edge of a padded arm table, and to pronate the forearm followed by immobilization in two U-shaped plaster splints or a circular plaster cast extending from the shoulder to the metacarpophalangeal joints. Operative treatment should be considered only when conservative methods have failed to give satisfactory results or when injury to the vessels or nerves have occurred.

Alcohol Sensitivity and Lymphogranulomatosis.—At a meeting of the Medical Society in Copenhagen, Dr. J. Bichel reported on observations at the radium station in Århus concerning the frequency with which patients suffering from lymphogranulomatosis show alcohol sensitivity. It is expressed by severe pain, paresthesia, a sense of oppression, giddiness, itching, dyspnea, shivering, ocular symptoms, nausea, and vomiting on the consumption of a little alcohol. The pain begins only a few minutes after a glass of beer is drunk, and lasts from 30 minutes to three or four hours, sometimes being severe enough to make the patient lie down or resort to drugs for relief. Since this phenomenon was first observed in 1948, all the 166 patients with lymphogranulomatosis coming to the Århus radium station have been systematically examined in a search for it. It was observed in at least 25 patients. At first attention was concentrated on pain, but later other symptoms came more into the foreground; in some patients there was no pain. The pain was usually referred to the area in which lymphogranulomatosis was in an active phase, and it was apt to be worst when the disease was situated in the bones, as it nearly always is when the disease has lasted for several years.

Although tests with small doses of alcohol in a search for alcohol sensitivity were systematically made on the other patients at the radium station, the disease was demonstrable only in one patient who did not have a lymphogranuloma. The reason why the phenomenon in question escaped notice for so long, in spite of lymphogranulomatosis being a well-known disease, might be that its victims were seldom studied in large groups as is now the case at Århus. Bichel's 25 patients all presented the histological picture of classic malignant lymphogranulomatosis.

Pancreatitis.—According to F. R. Mathiesen (*Ugeskrift for laeger,* Jan. 29, 1959) it has long been taught that operations for pancreatitis in an acute phase should be avoided unless there are doubts about its diagnosis, the patient being put on a fluid diet or, in severe cases, fed by parenteral injection with permanent gastric aspiration. Shock was combated by stimulation of the cardiovascular system, and peristalsis was promoted according to need. To see how this doctrine worked in Copenhagen's City Hospital the author checked the progress of the 171 patients treated between 1937 and 1956. Among the 82 men and 89 women 10 had died, 2 of the deaths being postoperative. Among the eight operated on in the acute phase two were suspected of appendicitis, two of intestinal obstruction, three of perforation, and one of incarceration of a hernia. Examinations of the bile ducts were made in 63% of the patients and only 38% of them showed signs of disease. The author's operation rate was low and his mortality was also low compared with those of other observers, hence his enthusiasm for conservative treatment.

Care of Invalids.—The poliomyelitis epidemic of 1952 left in its wake many paralyzed patients whose care in hospital has been costly and monotonous for the patients. A better alternative was found in the form of a 13-story collective house containing private apartments for patients and their families. Eugenie Engberg (*Ugeskrift for laeger,* Feb. 5, 1959) told how respirator patients can be reunited with their families after six years of hospital life. Planned and operated by the Ministry of Social Affairs in conjunction with voluntary organizations, this building has an institutional department on the top floor and 170 private apartments lower down. Special attention is given to the paid employment of relatives who, after a short training in hospital, can take over the responsibility for the daily welfare of the patients at a cost much below that of hospital care. To assist the patients' families sleeping facilities are provided in small private cubicles in the institutional department, in which a professional staff of nurses will be available. By June, 1959, the tenants of the collective house began to move in. Although 30% of the apartments will be reserved for paralytic patients, the remaining 70% can be taken by ordinary tenants whose presence can be counted on to give a normal air to the surroundings.

Niacin for Hypercholesteremia.—Since September, 1956, Dr. P. Eilersen and Dr. N. Hobolth of the Frederiksborg County General Hospital have been investigating the influence of niacin on the concentration of cholesterol in the blood. Their latest contribution to the subject (*Ugeskrift for laeger,* Feb. 5, 1959) concerns eight patients whose serum cholesterol levels were determined before niacin was applied. With 300 mg. per 100 ml. taken as the upper limit of normal, all patients had an elevated serum cholesterol level (over 350 mg.%) before treatment. The dosage of niacin was raised gradually from 0.25 Gm. thrice daily to 1 Gm. thrice daily for 4 to 72 weeks. In all but one patient there was an appreciable rise of the serum cholesterol level during this treatment, and when it was discontinued it fell to the pretreatment level. All eight patients experienced some discomfort at the beginning of treatment, in the form of a sense of heat and tingling of the skin, and two suffered from nausea and vomiting. Of the seven who had cardiac symptoms four found they diminished under this treatment. While niacin would thus seem to be capable of reducing the serum cholesterol level, its ability to prevent arteriosclerosis remains to be proved.

Scalenus Anticus Syndrome.—The scalenus anticus or cervical rib syndrome was discussed by Dr. O. Birn (*Ugeskrift for laeger,* Feb. 19, 1959) of the Sönderborg Hospital where 34 patients underwent scalenotomy for the relief of pain and other symptoms. Three of these patients had this operation on both sides bringing the total to 37 scalenotomies. On follow-up examination 19 were found to be rid of their symptoms and 15 were no better. Of these 15 further examination revealed the underlying cause of the symptoms in several. When first confronted by this syndrome, the surgeon should limit his treatment to infiltration anesthesia of the scalenus anticus, supplemented by physiotherapy and the correction of postural abnormalities. If the resulting benefits are brief, scalenotomy may be resorted to; if it fails the diagnosis should be revised in a search for an alternative explanation of the symptoms. Interpretations of this syndrome have fluctuated in recent times with the assumption, prior to 1927, that a cervical rib is always to blame. Since then growing attention has been paid to the scalenus anticus, whose resection has sufficed to banish the symptoms. In 1935 the syndrome was described in patients in whom no cervical rib could be found.

FINLAND

Spondylolisthesis.—At the orthopedic hospital of the Invalid Foundation in Helsingfors a series of 809 patients with spondylolisthesis or spondylolysis were observed. Reviewing these cases in *Nordisk medicin* for Feb. 26, Dr. L. E. Laurent noted that only 85 patients were admitted to hospital with a view to operation. With males slightly in the minority (46%) their numerical inferiority was most marked in the age group 40 to 49 in which there were 94 men and 149 women, possibly a reflection of the tendency to experience the symptoms of this lesion during the climacteric. Among the 809 patients were 10 whose lesion was discovered incidentally and in the absence of any symptoms. As many as 58 were less than 20 years old. In 52 the origin of the lesion was presumed to be traumatic. The operation was posterior fusion without exploration in 33, posterior fusion with exploration or laminectomy in 13, anterior fusion without exploration in 7, and laminectomy only in 32. A follow-up examination of 77 patients gave the impression that fusion is more effective than laminectomy without fusion. Only in exceptional cases should laminectomy be performed. Even when there are such serious symptoms as prolonged and obstinate pain with incapacity for work, no operation should be undertaken until conservative treatment has been given a fair trial.

Hepatic Cirrhosis.—At the Maria Hospital in Helsingfors Sundberg and Adlercreutz (*Nordisk medicin*, March 12, 1959) observed 226 patients with cirrhosis of the liver (141 men and 85 women) during the period 1945-1956. According to their histories 52 (23%) had a record of acute hepatitis, 89 (39.3%) of alcoholism, and 32 (14.2%) of syphilis. In several patients more than one of these factors may have been operative. While the cause was thus mixed in over 10%, unknown causes accounted for over 32% of the total. In the same period 159 patients with hepatic cirrhosis who died underwent postmortem examination. The causes of death in these patients were hepatic coma in 57 (35.8%), malignant tumors in 22 (13.8%), infections in 19 (12%), other diseases in 14 (8.8%), thrombotic disease in 11 (6.9%), gastrointestinal hemorrhage in 27 (17%), and other hemorrhages in 9. The authors concluded that hepatitis is a more frequent cause of cirrhosis of the liver in Finland than it used to be, but not to such a great extent as in England and Germany.

Acute Bacterial Meningitis.—A series of 379 children aged 14 days to 15 years with bacterial meningitis was studied by Jyrki Kauhtio and co-workers (*Nord. med.* 61:177-180 [Jan. 29] 1959). Neisseria meningitidis was the causal organism in 21%, Diplococcus pneumoniae in 20%, and Hemophilus influenzae in 29%. In 25% of the patients the onset occurred when they were below the age of 3 months, and 67% became ill during their first year of life. The gross mortality was about 70% among children under the age of 14 days, 45% among those 2 weeks to 3 months old, 25% among those 3 to 12 months old, and 16% among those who became ill after their first year of life. Well over 33% of the deaths occurred during the first 24 hours in hospital, and in view of this fact it was considered that the treatment of the initial shock at the time of admission was as important as the institution of specific therapy with antibiotics. As a guide to the choice of a suitable antibiotic the authors recommended, besides examination of direct smears, culture of cerebrospinal fluid and blood before starting treatment.

In meningococcic meningitis sulfonamides and various antibiotics were useful. In pneumococcic meningitis penicillin in massive doses was recommended, and in H. influenzae infection chloramphenicol was preferred. The latter drug was also found to be the safest in those patients in whom the causative organism remained unidentified. Intrathecal administration of antibiotics was unnecessary. With these therapeutic principles mortality in meningitis due to Neisseria could be kept below 5%, in meningitis due to D. pneumoniae below 15%, and in meningitis due to H. influenzae at 5 to 10%.

Routine Urine Testing in Women.—In 500 women nonsterile specimens of urine were first taken for routine examination by Antero Kasanen (*Nord. med.* 61:218-219 [Feb. 5] 1959). In 67.6% the sediment was normal on staining, containing less than four leukocytes per high-power field. In 16.8% the nonsterile specimens gave the same results as sterile control specimens, and in only 15.6% did the nonsterile specimens give a positive result which was not verified by sterile control. Because of the risk of infection at catheterization the nonsterile specimen was recommended for routine use. Only those showing positive results should be catheterized, in the author's opinion.

Funnel Chest.—If reconstruction of a funnel chest is considered indicated, operation should be performed early, since it is easier in younger patients, according to V. Paltia and co-workers (*Acta chir. scandinav.* 116:90-98, 1958/1959). The authors treated 70 patients by a method whose main features were transverse incision, freeing of the origin of the pectoral muscles, subperichondrial resection of the deformed costal cartilages, division of the xiphisternal joint, stripping of the posterior surface of the sternum, and stabilization by means of a metal strut introduced through the sternum with its ends resting on the costal stumps. The strut was removed after three months. The mortality was nil. Pneumothorax occurred as a complication in 11 patients and wound infection in 7. Because of a shift in position the strut was removed less than six weeks after the operation in 10 cases. The result, as estimated either at the removal of the strut or later, was considered good or satisfactory in more than 90%.

GERMANY

Vitamin C Levels.—Czok and Bramsel (*Klin. Wchnschr.* 37:195, 1959) determined the plasma vitamin C level in about 1,200 men and women. The object of these trials was to discover (1) seasonal variations in the vitamin C level and the occurrence of maximum and minimum levels, (2) whether the average vitamin C level in men is different from that in women, and (3) whether the vitamin C level of the persons investigated was satisfactory. Significant seasonal variations in the plasma levels of vitamin C were clearly established, minimum values being observed in May and maximum values in August. On the average, women had a vitamin C level of 0.97 mg.%, while in men the level was about 0.65 mg.%. The authors established a functional relationship between the vitamin C level and the vitamin C intake, whereby a daily intake of the recommended 75 mg. of vitamin C produced a plasma level of 0.85 mg.%. Assuming this to be a standard level, the tests showed that 65% of the men and 40% of the women had subnormal levels. It was concluded that the vitamin C intake of a large proportion of the West German population was less than 75 mg. daily.

Serum Lipid Levels.—Metabolic factors influence the pathogenesis of arteriosclerosis. As we grow older more and more lipids are deposited inside the artery walls. Hyalinosis, lipidosis, and calcinosis are three interrelated processes occurring in arteriosclerosis. Blood lipid values tend to increase in old age, but the increase in the concentration of lipids in the blood is not always concurrent with the changes in the walls of the vessels. Irrespective of the significance one may ascribe to serum lipid concentrations for the development of arteriosclerotic changes, the following facts cannot be ignored: Arteriosclerosis will appear earlier and in more severe form with diseases involving increased serum lipid and especially cholesterol levels, e. g., diabetes, nephrotic syndrome, hypothyroidism, and idiopathic hyperlipidemia or hypercholesteremia. The aging human being shows about the same tendency toward hypercholesteremia as toward arteriosclerosis.

The great scientific significance of metabolism for arteriosclerotic research justifies closer examination of the problem of controlling hyperlipidemia and hypercholesteremia. In the field of endocrine therapy estrogens and thyroid hormones have met with great interest. Experiments carried out by F. A. Pezold (*Ärztl. Wchnschr.* 14:125, 1959) showed that by oral administration of suitable doses of triiodothyronine the serum cholesterol concentration could be lowered. Such tests in humans, however, do not supply conclusive evidence as to whether it will be possible effectively to reduce lipid infiltration of the atheromatous vessel walls, as observed in the high cholesterol intake sclerosis of suitable laboratory animals.

NEW ZEALAND

Breast Feeding.—In the *New Zealand Medical Journal* (57:539 [Dec.] 1958) Drs. Deem and McGeorge reported that of 892 patients admitted to the Queen Mary Maternity Hospital, Dunedin, 76% left the hospital fully breast feeding, 14.8% partially breast feeding, and 9.2% bottle feeding their babies. Primary failure of lactation accounted for almost one-half the cases of artificial feeding on discharge. The various factors leading to later weaning were analyzed. Overdistention of the breasts was found to depend mainly on the volume of milk secreted and the elasticity of the breast tissue. Manual expression of the residual milk at the conclusion of each feeding, by ensuring more adequate emptying of the breasts, prevented the development of excessive milk tension in most patients with elastic breast tissue. A certain proportion of women had small, inelastic breasts which were liable to become overdistended, despite their milk production being inadequate to the needs of the infant. Manual expression also provided a means of estimating the total available milk production on the 4th, 7th, and 10th days of the puerperium.

It was found that the amount of milk taken by the infant was related directly both to his birth-weight and to the amount of milk available in the breasts and that of these two factors adequate milk production was the more important. An easy introduction to breast feeding on the occasion of the first pregnancy is most important as an encouragement to its continuation in subsequent pregnancies. Conversely, discomfort on the first occasion is likely to lead to subsequent antipathy to the procedure. It is important to realize that breast feeding is not an end in itself. Its object is to insure the best possible start in life for the infant, and when it becomes inadequate or difficult there should be no hesitation in changing to artificial feeding.

Hydatid Disease.—Dr. Foster (*New Zealand M. J.* 57:562 [Dec.] 1958) stated that the per capita incidence of hydatid disease is probably higher in New Zealand than in any other country in the world. As a cause of death it is nearly three times as common in New Zealand as in Australia. The New Zealand figure is 20 times greater than that for England and Wales, 78 times greater than that for Scotland, and 125 times greater than that for the United States. In New Zealand the average number of cases reported per year is 87. In a series of 902 patients the liver was involved in 431 (47.8%) and the lungs in 329 (36.5%). The third most common site was the abdominal wall, with 27 patients (3.0%). For patients under 20 years of age the lung was more frequently involved than the liver, but for all patients above 20 years of age the liver was the more common site. This pattern was more marked in the higher age groups. In the 11 years from 1946 to 1956 there were 156 deaths from hydatid disease. A most striking feature was that in hospital patients the disease was over six times as common in Maori men as it was in European men, while for women the disease was over four times more common in Maoris. It also seemed that people living in small towns had a much greater chance of contracting hydatid disease than those living elsewhere. The fact that the rates for forestry workers were higher than those for farm workers is somewhat surprising when it is remembered that a close association with dogs which are fed on raw sheep offal is generally considered to be the principal mode of transmission.

Mitral Surgery.—Drs. Borrie and Campbell (*New Zealand M. J.* 57:571 [Dec.] 1958) reported a series of 20 cardiac operations (17 mitral valvotomies in 16 patients, 2 explorations in patients with mitral regurgitation, and a successful cardiac massage for cardiac arrest during induction of anesthesia). Patients with pure mitral stenosis subjected to mitral valvotomy ranged in age from 15 to 58 years. Three of the patients were three to seven months pregnant. The outcome was successful, thus showing that if it is required for medical reasons valvotomy can be accomplished without any ill-effect as late as the 28th week of pregnancy. It removes a circulatory obstruction which might precipitate acute pulmonary edema at the onset of labor. Cardiac arrest occurred during induction of anesthesia in one patient and was successfully treated by transabdominal cardiac compression. A successful valvotomy was performed two months later. Restenosis occurred in one patient, necessitating a second valvotomy.

There were no operative deaths in the group of patients with pure mitral stenosis. There were three late deaths, one occurring 9 months and two 27 months after operation. The remaining 13 patients were well when last seen, had a greatly increased tolerance for effort, required no further treatment, and were considered to have achieved satisfactory results. The two patients explored had severe mitral regurgitation with heart failure. One had a cusp deformity of the posterior commissure. Despite successful splitting of the anterior commissure her regurgitation persisted and she died eight hours after operation. The other had a widely dilated valve ring with severe regurgitation. This finding formed the basis of experimental work on sheep to narrow the mitral ring by placing a circumferential suture around the mitral ring. These experiments, conducted in 1953 and 1954, evolved a method which was discovered independently and simultaneously by Davila and Glover of Philadelphia and has been successfully applied by them to human beings.

Whooping Cough Immunization.—Dr. Aicking (*New Zealand M. J.* 57:633 [Dec.] 1958) stated that immunization against whooping cough has been the subject of prolonged widespread controversy since it was first described by Nicolle and Conor in 1909. Deaths from whooping cough in New Zealand in recent years have exceeded those from diphtheria, scarlet fever, measles, and smallpox combined. The disease causes more childhood deaths than any other single communicable disease. The authors sent 540 questionnaires to parents of children in the 6-to-7-year age group in the Dunedin area, 460 of which were returned. The following conclusions were drawn: The incidence of whooping cough in Dunedin since 1950 was less than 25% in children up to 7 years of age. This was much lower than figures generally quoted in other countries and was only about 33% of the incidence reported in Dunedin in 1933. Almost 70% of children in the community had received *some* immunization against whooping cough. All but a few had had combined vaccine. Only 50%, however, had received a full course of vaccine.

The age of immunization was fairly satisfactory, 70% receiving it before their first and 90% before their second birthday. The value of immunization seemed clear-cut. Nonimmunized children showed an incidence of whooping cough 3.5 times greater than that of those who had been fully immunized. Unimmunized children were twice as likely to develop whooping cough after close exposure to other cases. Children receiving only two immunizing injections had an incidence double that of children receiving three injections. This indicates the importance of the third injection. There was some evidence to suggest that immunity tends to decrease two years after immunization. If this is true, an earlier booster shot might be of value.

UNITED KINGDOM

Poliomyelitis Immunization.—Parkins and co-workers studied the effect of a third or booster dose of poliomyelitis vaccine in a group of 80 infants who at the time of the primary immunization were aged 10 weeks or less (*Brit. M. J.* 1:680, 1959). The booster dose was given 10 to 12 months after the primary immunization. In 17 of the 80 a rise in antibody titer occurred between the primary immunization and the booster dose, suggesting that these infants became infected with poliomyelitis in this period. They were excluded from the assessment of the effects of the booster dose. Infants who showed an increase in antibody level after primary immunization responded to the booster dose, but they had low levels of antibody transmitted from the mother. Those who had high antibody levels at birth and gave no primary response did not react to the booster dose at 10 to 12 months. Some with intermediate levels of maternal antibody who had not reacted to the primary immunization did so when the booster dose was given. Evidently they were immunized by their first dose, but the rise in titer was masked by the maternal antibody.

Generally speaking, those infants who were immunized when 10 weeks old responded better to the booster dose than those given primary immunization at between 1 and 6 weeks. These observations showed that the immunization of infants against poliomyelitis in the first 10 weeks of life was unsatisfactory. This was particularly true of the response to type 1 virus. The authors believed that the earliest age for mass immunization against poliomyelitis should be 6 to 9 months.

Psychiatric Research Urged.—The government should enable more scientists to embark on mental health research work, according to Ian T. Henderson, who spoke at the annual meeting of the Mental Health Research Fund in London. In four years the fund has made grants to 48 research workers. The quality of applicants for grants is high and the competition keen, but at present a research career in mental health offers few opportunities and rewards. Although mental patients fill one-half the hospital beds in Great Britain, the volume of research in this field is meager compared to other branches of medical research.

Shortage of Chiropodists.—Statutory registration for chiropodists is more than ever necessary, according to a spokesman for the Society of Chiropodists, if enough qualified men and women are to be available to run the new National Health Service foot clinics. Freedom for local health authorities to start such clinics was announced by the Minister of Health. It will be difficult, however, to find enough qualified people to staff the new clinics. The few local authorities who already have such services have great difficulty in recruiting trained chiropodists. About 90% of the qualified members of the profession are private practitioners. It might be better to leave them as such and to have patients in need of chiropody obtain it through their family doctors. The new service should be based firmly on medical need. The patient suffering from diabetes or some other disorder should be given priority over the healthy woman with corns which, though admittedly painful, are due purely to "shoe-vanity." The physically handicapped, for whom the Minister recommends priority, will need to be closely defined, otherwise a full national service will be attempted, and there are neither the personnel nor the facilities for it.

Establishment of foot clinics on a country-wide basis would involve heavy expenditure in buildings, equipment, and staff. It is doubtful how many chiropodists in private practice would be prepared to abandon their practices to staff the new clinics. Much pioneer work in the provision of chiropody for the elderly has been done by voluntary organizations. After April 1, 1959, local health authorities were free to contribute to the funds of such organizations for the purpose of providing foot treatment for the elderly. The chiropody service was criticized by the National Corporation for the Care of Old People, because the patient could not go to the chiropodist of his choice, and there might not be enough clinics in some areas. No mention has been made of a domiciliary service, and for the aged this would be an important aspect. Many elderly people are housebound, sometimes largely because of the condition of their feet. A special scheme for domiciliary chiropody was tried in Dorset. The cost of a service for older people would be about $4,900,000 a year. This is not unduly large if it keeps older people mobile and independent.

Hospital Construction Plans.—Britain's physicians are pressing the government to embark on a 10-year plan of new hospital building costing 2.1 billion dollars. The scheme is the work of two surgeons, Mr. A. Lawrence Abel and Mr. Walpole Lewin (*British Medical Journal,* supplement, April 4, 1959). It is not so much more beds or more staff that are required, but up-to-date buildings constructed for present-day medicine and not for medicine of 100 years ago. The General Medical Services Committee, which negotiates for the 20,000 general practitioners in the National Health Service (NHS), urges increased access of general practitioners to hospital beds. Before the government is approached the report will be considered at the British Medical Association's annual meeting in Edinburgh in July.

The cost of the NHS is a constant worry, but people are beginning to recognize the fact that some of this cost is due to the enforced and uneconomic use of outworn buildings. Cheap buildngs and temporary constructions prove extremely costly to maintain. It has been estimated that $2,800,000 spent on modernization schemes involves an extra $1,120,000 in subsequent running costs, whereas $2,800,000 spent on new hospital building leads to only $420,000 extra in running costs.

Since everything cannot be done at once, the first priority would seem to be to insure that in every large population area there is one efficient general hospital with a 24-hour resident medical and nursing staff. Although we need new hospitals, this does not necessarily mean that we need more hospitals. It may be that more old hospitals need to be pulled down than new ones built. New towns where there are no hospital services should have first priority. Old people's homes, more home nurses, and other services for the elderly could reduce the demand for hospital beds. Some patients do not require full nursing facilities, and for them a special wing should be run more on hotel lines, with a cafeteria and only basic supervision.

New Fellows of the Royal Society.—Among the 22 new fellows of the Royal Society are several physicians. Dr. J. F. Tait and his wife were elected fellows in recognition of their work on adrenocortical hormones. In 1952 they discovered aldosterone by chromatographic fractionation of the adrenal cortex. Prof. Franz Bergel was given the fellowship for his work on synthetic organic compounds in the fields of vitamins and cancer. His early work was on the chemistry of aneurine, riboflavin, pyridoxine, lysergic acid, and anticholinesterases. More recently he has been engaged in the synthesis of cytotoxic drugs for the treatment of malignant disease. Dr. D. W. Henderson was elected in recognition of his investigations on the transmission of organisms causing respiratory disease in experimental animals. His work has thrown light on the size of infecting particles and the spread of infection. Dr. Ann Bishop received her fellowship for contributions on drug resistance in the chemotherapy of malaria. Dr. R. D. Keynes was elected for his investigations on the transmission of nervous impulses. Drs. F. H. Crick and M. F. Wilkins have been working on the molecular structure of desoxyribonucleic acid and the protein molecule.

Medical Students on Medical Education.—In one of the papers in the final examination in medicine at Manchester University, the candidates had a choice of one of six essay questions. Black analyzed the essays written on the subject of improvement in medical education (*Lancet* 1:673, 1959). The students demanded a broad general education, including languages, and a firm grounding in science. The course in anatomy came under fire. The commonest complaint was that principles were lost in a mass of detail, and it was suggested that dissection could largely be demonstrated rather than performed. If this were done the preclinical course could be shortened, provided applied anatomy and physiology were taught in the clinical period. Some students stressed the importance of surface anatomy; others saw no reason why medical students should learn any more anatomy than students of physiotherapy or even nursing.

Suggestions were made that teaching and examinations in pathology, bacteriology, and pharmacology should be completed in an extended preclinical period. Some students thought that the emphasis in pharmacology should be laid more on practical therapeutics. Nearly all the students considered that opportunities for residence in or near the hospital should be increased, so that more emergency work and practical procedures could be performed. It was generally thought that students should be given more responsibility with the patients. There was some difference of opinion as to the most suitable time for demonstrating physical signs. Some thought that these should be learned as soon as possible; for example, during the first clinical appointment.

Another majority opinion was that much more time should be given to training in general practice. Three months of work with a general practitioner was suggested. According to some students more emphasis should be placed on instruction on sexual matters and the study of mental disease and drug addiction. It was suggested that attendance at lectures should be voluntary and that many of the lectures should be replaced by a tutorial system. One of the most revolutionary suggestions was that all examinations should be replaced by tutors' reports.

Siamese Twins Separated.—Siamese twins, joined by the crowns of their heads, were successfully separated by a neurosurgical team headed by Dr. J. O'Connell, at St. Bartholomew's Hospital, London. The twins were two of triplets born in May, 1958. Preliminary radiologic investigations were made to determine the position of the main blood vessels in the brains of the two infants. The chief difficulty, which had been foreseen, was the anatomic arrangement of the cerebral vessels and the possibility of hemorrhage from them during and after the separation. A preliminary operation was performed to fashion skin flaps to enclose the separated heads. Some freeze-dried dura mater to cover the separated brains was flown to the hospital from the United States Naval Medical Center at Bethesda, Md. The final operation took nine and one-half hours. The babies were given daily physiotherapy before the operation, as their union had prevented them from making many of the movements normal in infancy. The infants survived the operation. Their heads, however, became heavily infected, and one of them developed meningitis

12 days later. This was controlled by chemotherapy. Should the infants eventually survive they will wear caps of reinforced material, like motorcyclists' crash helmets, to protect the brain until the skull stops growing. Then they will be provided with metal skull plates of tantalum or Vitallium.

Anticoagulant Therapy After Cardiac Infarction.—The Medical Research Council (MRC) conducted a controlled clinical trial to assess the value of long-term administration of anticoagulants after a cardiac infarction (*Brit. M. J.* 1:803, 1959). Although there are many reports in the world literature there have been few controlled trials, and most of the pioneer studies can be criticized because of the heterogeneity of the clinical material, the use of "historical" controls with inadequate matching, failure to use strictly random series of patients, and failure to take into account both timing and duration of the period of exposure to the risk of recurrent infarction and death during the follow-up of the groups being compared. In the MRC trial 383 patients who had recovered from the acute phase of a cardiac infarction of defined severity were classified according to their previous infarct history and allocated at random in a hospital center to one of two groups. The patients of one group were given the anticoagulant phenindione in doses large enough to increase the prothrombin time (measured by Quick's one-stage method) by 2 to 2.5 times. The other control group received tablets of similar shape and size but containing only 1 mg. of the anticoagulant, which is a therapeutically ineffective dose.

Both groups of patients were seen at regular intervals of two to three weeks and clinically assessed more fully by radiologic and electrocardiographic methods every three months. Rigid diagnostic criteria governed inclusion in the trial. Q-wave evidence of infarction was essential. The age range was from 40 to 69 years, and treatment began within a month of the diagnosis of infarction. Patients who had recovered from the acute phase of a cardiac infarction of defined severity were subdivided according to their previous infarct history and then randomly allocated to one of the groups. Patients were excluded from the trial if they had any nonvascular condition likely to cause death within two years; if they had had a hemorrhage from any cause in the previous six months; or if they suffered from malignant hypertension, peptic ulcer, valvular heart disease, cardiac failure, or syphilis. Patients taking large doses of salicylates, which affect the prothrombin time, were also excluded.

Three indexes of the effectiveness of treatment were used, namely, death from all causes from cardiovascular disease in general and from recurrent myocardial infarction in particular; frequency of myocardial reinfarction of varying degrees of severity; and subsidiary data on return to work and the presence or absence of anginal pain or dyspnea at the time of the last examination. The follow-up period was one to three years. Of the men in the control group 18% and in the group treated with phenindione 10% died during the follow-up period. The difference was not statistically significant. The corresponding figures for women were 17 and 11%, also not significant because of the small numbers. When infarcts serious enough to cause permanent withdrawal from the trial were added to deaths as a combined index of therapeutic success or failure, there was a significant reduction in their frequency in men, particularly in those under 55 years of age receiving the therapeutic dose of the drug. Under the age of 55 treated men suffered recurrent infarctions at only 20% of the rate of the controls, and over that age the rate was halved in the treated group. The difference in the death rate in the treated and untreated groups was most evident in the first six months of the follow-up period. The disparity in the reinfarction rate was maintained for at least two years and persisted longer in the treated men than in those of the control group who returned to work. As would be expected there were more hemorrhagic complications in those receiving therapeutic doses of phenindione than in the controls.

Radioisotopes in Drinking Water.—The fall-out of radioactive strontium and radioactive cesium in rain has been measured for the last five years, but not much is known about its effects on the supplies of public drinking water. The Atomic Energy Research Establishment at Harwell published the results of some preliminary investigations which show how these isotopes have penetrated certain drinking water sources (Preliminary Survey of Radio-Strontium and Radio-Cesium in Drinking Water in United Kingdom, Her Majesty's Stationery Office, 1959). Tests were made of lake waters in seven large areas (Liverpool, Manchester, Leeds, Birmingham, Cardiff, Glasgow, and mid-Northamptonshire). The mean level of Sr^{90} in these waters was 0.45 $\mu\mu c$ per liter, which represented about 15% of the content of rain water at that time. There were differing ratios between Sr^{89} and Sr^{90} which reflected the effect of reservoir storage on the age of the water. River sources supplying Coventry, Oxford, and London had a mean Sr^{90} content of 0.24 $\mu\mu c$ per liter, or about 10% of that of the rain water. Well waters supplying Wolverhampton, Cambridge, and Brighton had very low values for Sr^{90}—less than 0.01 $\mu\mu c$ per liter. This was less than 1% of that in rain. The highest level of radioactive cesium was in river water. If the ordinary person drinks 1.5 liters of fluid daily, these lake and river waters would contribute an extra 10% of Sr^{90} to the diet. The contribution of well waters would be negligible.

CORRESPONDENCE

TREATMENT OF GONORRHEA

To the Editor:—A story in the *New York Times*, March 7, is based on the article "Failure of Penicillin in Treatment of Acute Gonorrhea in American Troops in Korea," by Capt. Ernst Epstein, in The Journal, March 7, 1959. The Journal reached me on March 10, 1959. I should like to comment on the article.

Penicillin-resistant urethritis due to proved Neisseria gonorrhoeae is nonexistent. This holds for every place in the world; I have visited practically every capital and many not so important centers on the six continents and Japan. Urethritis resisting adequate dosage of penicillin was not, and the persistent discharge after adequate dosage of penicillin is not, due to gonococci. Adequate penicillin dosage consists of injection of the content of a vial of procaine penicillin G in oil with 2% aluminum monostearate, labeled as containing 3 million units. A variation to 10% at the time of bottling is permitted. Laboratory and clinical bases sustain this practice. Warfield Garson, M.D., in his paper on "Evaluation of Gonorrheal Therapy," presented at the U. S. Public Health Service Venereal Disease Seminar at Detroit, Feb. 20, 1957, said: "I cannot resist the temptation to bring to your attention the fact that those organisms showing a sensitivity above 0.2 [units per ml.] would be potential treatment failures when given the usual 600,000 units of Bicillin by intramuscular injection. . . . The parenteral use of 1.2 million units of Bicillin (All Purpose) will, on the other hand, give a level in excess of the highest in vitro minimum inhibitory concentration of the gonococcus for a period of approximately twelve hours and will remain in excess of 0.2 units per ml. of serum for at least twenty-four hours. . . ." Garson recognizes "the dangers involved in assuming in vitro results to be necessarily valid in the in vivo situation."

Garson quotes Preston and Dunsworth: "These authors, working at the County Health Department in Columbia, S. C., undertook to find the reason for high treatment failure rate of gonorrhea in females. . . . They conclude that 1.8 million units of PAM is necessary for an acceptable rate of cure of gonorrhea in females. . . . It was demonstrated that penicillin when applied to the medium (HeLa cells and rabbit fibroblasts) would kill the extracellular gonococci but would not affect the intracellular organisms." Garson is certain from the results of the laboratory and clinical findings that "we should raise our dosage sights for the routine treatment of gonorrhea, at least in females."

Captain Epstein writes: "The fact that bacterial culture studies were not done will no doubt be held by some as contributing to failure to establish the diagnosis." Work by Durel and others in Paris, reported in French publications, proves that urethritis in the male is associated with diplococci identified by fermentation tests as Neisseria meningitidis and the little known Neisseria pharyngis sicca (at least two types). Neisseria catarrhalis and Diplococcus crassus are found in urethritis of the male. The dictum of 1939 is condensed in the sentence: "A gram negative diplococcus present in the discharges from an acute purulent urethritis is the gonococcus." This concept is neither accepted nor acceptable in 1959!

Epstein's paper has this provocative paragraph: "It should be pointed out that reinfection cannot possibly explain treatment failures in patients in whom N. gonorrhoeae [only on morphologic and tinctorial evidence—H. G.] was demonstrated in the discharge while the patient was on penicillin treatment. The daily dose of penicillin used is several times as great as the amount needed for effective prophylaxis of gonorrhea."

It is recognized that N. catarrhalis, N. pharyngis sicca, and D. crassus do not respond to any dosage of penicillin. Experience everywhere proves that no one of the modern antibiotics destroys nonbacterial causes of urethritis in the male. They are in the domain of the urologist.

I am often asked, in distant geographical areas, to discuss failure of penicillin therapy in the treatment of urethritis. Laboratory studies in these areas do not include the fermentation tests for biological properties of the neisseriae. Hence, the title of Epstein's paper should be "Failure of Penicillin in the Treatment of Acute Urethritis." Reference to N. gonorrhoeae as the cause of penicillin-resistant urethritis should be deleted.

I deplore the prepublication newspaper accounts based on the article in The Journal. The damage is beyond estimate. The hopes of thousands of infected persons rightfully entitled to adequate dosage of penicillin, dashed to the ground, can be restored by competent discussion and equal publicity in the nonmedical press.

Herman Goodman, M.D.
18 E. 89th St.
New York 28.

To the Editor:—Dr. Goodman's letter raises several points which I would like to answer. I have questioned dozens of military physicians in Korea and Japan, and everyone who had personal experience in treating gonorrhea commented on the problem of penicillin treatment failures. Curtis and Wilkinson (*Brit. J. Ven. Dis.* 34:70-82 [June] 1958) document their experience with the bacteriology of penicillin failures in gonorrhea. Their studies, as well as the discussion appended to the paper, indicate that penicillin-resistant cases of gonorrhea are being encountered in Britain. Bernstein, of the 406th Medical General Laboratory at Camp Zama, Japan has intensively investigated the bacteriology of penicillin treatment failures. Using rigid laboratory criteria he proved that these were indeed Neisseria gonorrhoeae *infections* and that the in vitro penicillin sensitivity of these strains was definitely, although moderately, elevated.

By measuring in vivo penicillin blood levels, Bernstein showed that the usual penicillin schedules failed to produce bactericidal penicillin levels against resistant strains. He suggested more massive amounts and recommended that 900,000 units of aqueous suspension of procaine penicillin G be given in each of two daily injections, three hours apart, for three days—a total of 5,400,000 units. This regimen has been very successful. Kern treated more than 50 consecutive patients in this manner with but one failure. Grosshandler increased Bernstein's schedule to 1,200,000 units at each injection and had no failures in a series of about 70 patients with gonorrhea.

I treated 85 consecutive patients who had gonorrhea with an aqueous suspension of crystalline procaine penicillin G alternately by one of three methods: (1) 600,000 units daily for five days (29 patients); (2) 600,000 units twice daily, 12 hours apart, for five days (28 patients); and (3) 900,000 units twice daily, 3 hours apart, for three days (28 patients). There were four failures in group 1 (14%) and four failures in group 2 (14%), but in group 3 there was only one failure (4%). While not statistically overpowering, these results agree with those of others and indicate that if high enough penicillin blood levels are achieved, penicillin failures are infrequent.

Dr. Goodman believes that the cases of penicillin failure are actually cases of nongonorrheal urethritis misdiagnosed as gonorrhea. He notes that the factors causing nongonorrheal urethritis do not respond to penicillin. With this I agree. If we are misdiagnosing nongonorrheal urethritis as gonorrhea, increasing the amount of penicillin should have no effect on the failure rate. The virtual elimination of penicillin failure with massive penicillin therapy also eliminates Dr. Goodman's explanation.

The purpose of my paper was to call attention to a phenomenon which had not been adequately reported in the literature. It was carefully pointed out that the failures occurred with penicillin dosages generally considered more than adequate. No statement was made that other antibiotics were to be preferred to penicillin or that penicillin in other schedules would not be curative. I still believe penicillin to be the drug of choice in treatment of gonorrhea, and when resistant strains are encountered the routine penicillin treatment should be modified along the lines recommended by Bernstein. Ideal penicillin schedules in these circumstances remain to be defined.

MISCELLANY

SO YOU HAVE BEEN ELECTED

A MESSAGE FOR NEW OFFICERS OF COUNTY MEDICAL SOCIETIES

David G. Welton, M.D., Charlotte, N. C.

You have been honored by the recognition received from your colleagues and your community, and you are wondering how to go about the year's activities—what goals to try to attain. Like other golden opportunities yours offers a few traps along the way. Beware of the attitude of some when elected to a high office by colleagues—the belief that above all you must avoid conflict and controversy and have a nice, smooth, pleasant year. This—if accomplished—may be pleasant, but it is stagnation, and in the medical profession we cannot afford stagnation. We have never tolerated it scientifically and we must not tolerate it in the programs of our county societies. This magnificent country was neither created for nor built by people who feared conflict and controversy. These are unavoidable by-products of progress.

From my own experience there is hardly such a thing as a "noncontroversial subject" in a county medical society; I found that not all of my colleagues could agree even on the matter of celebrating the 50th anniversary of our society. Constructive projects and programs, when carried out, will strengthen you, your society, and organized medicine as a whole, in spite of opposition which may be encountered along the way. Mr. Ralph Cordiner, president of General Electric Corporation, recently said, "Civilization is moved forward by restless people, not by those who are satisfied with things as they are." This applies perfectly to the medical profession today.

I can say in all earnestness, with no hesitation and no exaggeration, that the opportunity ahead of you right now, particularly those of you who are serving this year as presidents of your societies, is the biggest opportunity for service to your colleagues that you will have in your lifetime. More can be accomplished at the county level than at any other level of organized medicine. The officers and staffs of our state and national organizations perform chiefly policy-making and administrative duties and provide materials and technical assistance for us to use at the grass-roots level. But it is up to us at the county level to put these plans and policies into effect and to make a success of them. Why? Because we operate on a person-to-person basis daily. We have a direct personal relationship with each of our colleagues in our respective societies and with each of our patients.

You will soon realize that the honor of being president or secretary is paralleled by responsibility. There are times when you must speak and

---

Read before the Conference of County Medical Society Officers and Committeemen, Pinehurst, N. C., Jan. 10, 1959.

act in the name of the membership without consultation. Do not be afraid to do so. Have confidence in yourself; after all, your colleagues have confidence in you, and that is why you have been elected. I repeat: serving your county medical society is the finest opportunity for group and community service you will ever have; make the most of it. Dedicate yourself this year, and set aside some time regularly every week for county medical society work.

This means at least one afternoon and one evening a week, perhaps more, depending on the size of your society and the extent of your program. It means time on Sundays, particularly since this is a legislative year and you must do some visiting with our state legislators. Certainly this will be a *sacrifice—you will rob most of this time from your* family, some from your hobbies, and some from your practice; but taking this time, investing it regularly, and using it productively will make the difference between a successful officer with a year of accomplishment and a mere figurehead. What is the difference if you make a little less money? That will mean less tax. What you will gain cannot be measured in dollars and is tax-free. Service to others is the best protection against monotony and selfishness, just as occasional participation in a scientific program is insurance against intellectual stasis.

Some of you may be tempted to depend on a "one-shot deal" to make your year a success. I mean one big effort during one week or one month. Let me illustrate by telling you about a Protestant minister who was having difficulty filling his church. He decided that what would help most would be a revival meeting featuring a big name singer. With the help of his church leaders he arranged this and obtained Tennessee Ernie Ford to sing. Tennessee Ernie came, the church was filled, and he sang a fine program. After he finished "When the Roll Is Called up Yonder, I'll Be There," people streamed down to the front and the triumphant preacher signed up 200 new members. In an effort to meet this competition the Catholic priest across the street arranged a similar occasion and obtained Perry Como as the big attraction. Again, his church was packed and Perry sang a beautiful program, closing with "Ave Maria." Women wept and fainted; men and women came forward, and the excited father signed up 250 new members. The following week these two clergymen were having lunch with the rabbi in their town and boasted about their recent successes. When the rabbi heard of the surprising response they had achieved, he hustled back to his office, got busy on the telephone, and finally obtained Eddie Fisher for a big evening service. Members of his congregation advertised and promoted this occasion, and the synagogue was packed; people were sitting on the window sills. Eddie sang a fine program, closing with "There's a Gold Mine in the Sky," whereupon one-half of those present left immediately and went to the airport. So never put all of your "program eggs" into one event. I am confident that you all know it will take persistent and consistent effort throughout the year to achieve what you ought to and want to accomplish.

Committees

As an aid to planning, coordinating, and assigning jobs I have found it convenient to group committees as follows: (1) those committees which serve your society, (2) those concerned with public relations activities, and (3) advisory committees.

Service to Your Society.—The service group includes the board of censors and committees for orientation of new members, grievance, nominating, programming, finance, entertainment, welfare, and hospital relations. Your board of censors, which passes on new applicants, has a serious responsibility in checking their credentials, but the job should not end there. It should include orientation, which means getting the new doctor acquainted with the other physicians in your society, with the medical facilities in your community, and with the general range of fees in your community. This last point is especially important.

Grievance committees have proved their value; if your society does not have one, start one. Detailed information about how to do it can be obtained from state societies and from your neighboring societies.

In all these committee assignments and in the organization of your society keep in mind the value of continuity. Sometimes this may require a change in your bylaws; if so, have them changed. Continuity is particularly important in the board of censors and the grievance, finance, and public relations committees. In order to achieve it it is best to have staggered terms of more than one year each. This will prevent your starting out each year with inexperienced men on important jobs.

Public Relations.—It is important to have a basic public relations committee, plus subcommittees to take care of emergency and information service; legislation and public health; press, radio, and television; insurance; youth service; community fund drives; diabetic detection committee; and any special projects that come up. Depending on the size of your organization you may set up a subcommittee for each of these or you may have to depend on members of your single public relations committee to take care of one or more of these functions.

You have just been supplied with a check list of public relations activities. Few societies can do everything on this list, but you should keep increasing the number of these activities in your program each year. I would like to pass on to you what I consider the best definition of public relations, which comes from Mr. William Neal of Winston-Salem, N. C., a highly respected leader of public relations in the banking industry. "*Public* relations is doing those things in a continuous and organized way which will bring public understanding, approval; and support. It is based on (1) good performance, and (2) effective interpretation." This can be the keystone for your entire society's program.

All of us have been brought up on good performance; it is the effective interpretation that we do not know enough about. In the last few years, however, organized medicine has approached this matter in a realistic and constructive manner. All you have to do now is ask; your state society and the American Medical Association will supply you with more good material than you can digest. I strongly recommend this to every one of you—get a little indigestion this way. We must not sit back now and let the wind blow, ignoring attacks on us. Likewise, the defensive is a poor position in the public's eye. We must take a positive stand and coöperate with the various mediums which disseminate information to the public.

Advisory Committees.—The third group of committee functions is served by the advisory group, including such things as membership on the boards of local chapters of the American Cancer Society, the heart associations, the chamber of commerce, the women's auxiliary, Red Cross organizations, and local boards of health.

At first you may ask what business the medical society has in all of these organizations. You may be reluctant to participate in all of them, but the fact is that when one of these groups asks you for representation and help, you should be flattered. We have all heard a great deal about the loss of prestige and respect of the physician in his community during the past 30 years; therefore, when we get a request like this, it shows that people still have a healthy respect for us and look up to us, and it is up to us to maintain this desirable position by participating and lending a helping hand where we can. This will take time, but it will be time well invested for everyone concerned. The enthusiastic acceptance of such a request is in itself a positive public-relations step in the right direction, and many times it turns out that you have to spend less time than you expected.

I want to emphasize the importance of an active relationship with your local chamber of commerce. Remember that the future of private practice in this country probably lies in the legislatures of our states and in our congress. We have been told by experts that we must increase our contacts with our legislators. In addition to reaching them in organizations of physicians, the impact will be increased if we join in the chamber of commerce in each of our communities and, through them, the United States Chamber of Commerce. This organization, locally and nationally, represents all business and professional men. In most of the social and economic issues facing us businessmen agree with us. It will help our position and improve the effectiveness of our efforts if we join with each chamber of commerce locally and help them with their legislative efforts. Join your chamber of commerce, get your colleagues to join, see that you have good executive personnel, and help them improve their programs.

Efficiency and Cooperation

A word about the actual running of your meetings: It is important to establish and to maintain high organizational morale. Run a well-knit organization, what the navy calls a "taut ship." Keep the key men on their toes with frequent contact; by putting your time in and working hard regularly you will inspire them to do the same. You must have efficient cooperation in order to get results. Go to each meeting with a prepared agenda and an order of business conforming to your bylaws. Be familiar with each item on the agenda before the meeting is called to order; know parliamentary procedure. Your time and the time of each member of your society is valuable; having things organized ahead of time will do much to prevent aimless discussion and waste of time.

In looking ahead, I believe your main problem is going to be getting a sufficient number of your colleagues to work with you. Sir William Osler pointed this out many years ago: "By far the most dangerous foe we have to fight is apathy—indifference from whatever cause, not from a lack of knowledge, but from carelessness, from absorption in other pursuits, and from a contempt bred of self-satisfaction." So be prepared for it, do not be discouraged by it, and have a plan to meet it. Remember, and remind them, "you can't hit the ball with the bat on your shoulder, you've got to get out there and swing!"

In closing I want to emphasize three main points: 1. Have a positive program. 2. Get your colleagues to work with you. 3. Work hard at your program and have some fun while you're working. A short verse from Emerson is appropriate:

Life is too short to waste
In critic peep or cynic bark,
Quarrel or reprimand:
'Twil soon be dark;
Up! Mind thine own aim, and
God speed the mark!

IN MEMORY OF ALEXANDER VON HUMBOLDT

Walter K. Frankel, M.D., Newark, N. J.

Alexander von Humboldt, a renowned scientist, died 100 years ago on May 6, 1859. Ninety years ago the leaders of official, scientific, and intellectual circles of the New England states assembled in Boston to honor the 100th anniversary of his birth. The main speaker at that celebration was Louis Agassiz, world-famous American scientist, who had developed in the thoughts and ideas of Goethe and von Humboldt. *Oliver Wendell Holmes*, Harvard's eminent pathologist and man of letters, read a long poem on Humboldt, comparing him with Napoleon but giving the laurels to Humboldt whose scientific conquests on three continents were peaceful ones; Ralph Waldo Emerson said of Humboldt that he had bound together the continents. For more than four years he explored the unknown parts of Central and South America where he was the first to climb the Chimborazo, one of the highest mountains of our globe. When he returned to the United States from this expedition in 1804 he was the honored guest of the President of the United States, Thomas Jefferson, at Monticello. A year later he stood on top of Mount Vesuvius, beside him one of his greatest admirers, the youthful Simon Bolivar, who became the great *liberador*. And 25 years later, at the request of his friend Alexander, the Russian Czar, Humboldt made his famous 90-day expedition from St. Petersburg to the Chinese border and along the Himalayas, the Siberian steppes, and the Caspian Sea back to the Russian capital. As a result of this unique scientific expedition Russia established meteorological observation stations from the Neva to the Bering Strait.

Humboldt contributed also to scientific medicine. In Goettingen he learned anatomy under the great anatomist Blumenbach, and in 1797 he published a physiological study, "Experiments on Irritated Muscle and Nerve Fibre with Considerations on the Chemical Process of Life in the World of Animals and Plants," in which are enumerated more than 4,000 experiments, many of them made on himself. In that year he was in Jena, in close contact with Goethe and with Schiller who, as a former military surgeon, was interested in physiological problems. While Humboldt was preparing an expedition to the West Indies he again took up the study of anatomy. He told a friend that he often worked six or seven hours a day under the supervision of Professor Loder, who also was Goethe's instructor in anatomy, dissecting human bodies.

In his first book after his return from the "equinoctial Americas," his "Views of Nature," published in 1807, Humboldt reported on quinine from the Chinese forests of Loxa, with an impressive history of its medical use, and on the use of curare as a muscle-paralyzing poison, of which he brought the first plants to Europe. In "Kosmos," his great work published in four volumes between 1845 and 1858, and finished one year before his death, he gave a historical review of the development of Arabian medicine from the 10th to the 15th centuries.

Goethe often pointed out how Humboldt stimulated his own scientific studies—many of them in the field of medicine—but the great influence of Goethe on Humboldt was acknowledged in a letter in which he said that "in the forest of the Amazone River as well as on the crest of the high Andes" through Goethe's ideas he "became elevated, nearly provided with new organs."

MEETING OF THE AMERICAN COLLEGE OF PHYSICIANS

At the Chicago meeting in April the American College of Physicians for the first time in its history held a special symposium, not primarily for doctors, but for about 200 business executives and community leaders. One purpose of this symposium was to acquaint these lay leaders with the functions of the internist, a specialist whose professional qualifications and procedures are not generally as well understood as those of, for example, the surgeon or the dermatologist. The subject was "The Care and Preservation of the American Executive." Dwight L. Wilbur, president of the college, was moderator. Dr. Walter L. Palmer, Chicago, outlined the benefits derived from medical research in the last 25 years.

Dr. William C. Menninger, Topeka, Kan., speaking on emotional disturbances said that hate in the form of resentment, selfishness, and jealousy causes most of the world's troubles. Our mental health depends on how we individually handle these emotions. Although we cannot always rise above our hatreds we should not let them dominate our lives. To do so is to become trapped in the pursuit of unimportant goals from which no real satisfaction can be derived. Other important factors in mental health are having a hobby you get real fun out of, taking pride in your work, and having in addition to your work a constructive mission so big that it cannot possibly be completed in your lifetime. Whether we like to admit it or not, we must strive for security throughout our lives; if we achieve it too completely, we will lose our zest for life.

Dr. Chester M. Jones, Boston, said that about 0.4% of the adults in the United States now have some form of cancer and 25% of them will have it at some time in their lives. He predicted that steady progress in both the prevention and the treatment of cancer would be made. Dr. Irvine H. Page, Cleveland, said that to avoid a heart attack the average executive should get more physical exercise, avoid overweight, and take steps with the advice of his doctor to reduce his blood pressure if it is abnormally high. He advised that we avoid excesses but not miss anything.

Dr. Henry L. Bockus, Philadelphia, urged executives to be more alert to early signs of mental fatigue which can lead to premature senility in themselves and their junior assistants. He wished to revise the oft-heard statement that a man is as old as his arteries to read, a man is as old as his weakest vital organ. With regard to forced retirement he said that no one should ever retire from an active interest in service to others, in the life of the community in which he lives, and in the occupation to which he has devoted the major part of his life. The symposium was received with such enthusiasm that it may become a regular feature of these meetings.

THE LEISURE CORNER

COLLECTING WALKING CANES

The collecting of walking canes is a fascinating hobby. Private collections of canes usually average from 25 to 50 sticks but often run into the hundreds. The hobbyist's interest in a particular cane will center on its origin, the manner in which it was obtained, the material of which it is made, or the history of its former ownership. The cane collector may have inherited the object of his pride, received it as a gift, or made it himself.

An unofficial cane census for the United States taken not many years ago revealed that there are more than 5,000 canes in private collection, more than 10,000 in museums, and several million in actual daily use. No doubt the number has increased considerably since the estimation. Of course, canes are most helpful to persons temporarily or permanently disabled; but the universal appeal of the walking cane lies in its leisure use.

The word "cane," incidentally, was first applied to the walking stick about 1540, when a cane was made, "garnished with gold having a perfume container in the top" as well as other conveniences. Many centuries before there were evolved from the cave man's club different staves, from 5 to 6 ft. in length, including the shepherd's staff for guiding and directing straying sheep, the pastoral staff which served as an emblem of episcopal authority, and the pilgrim's staff, with a knob placed in the middle for a grip. Gradually, the length of the staff was reduced so that the holder could grip it at the top, and as a result cane makers began to make attractive handles of porcelain, ivory, and such costly metals as gold and silver.

Next the inventive cane makers devised conveniences to be concealed within the handles, such as weapons, spectacles, and perfume and medicine bottles. Sword or dagger canes found immediate favor with some sportsmen, as did gun or pistol canes. The decanter cane, which had wide appeal, was hollow inside and fitted with a glass tube in which a quart of liquor could be stored. From County Wicklow in Ireland came the shillelagh, a blackthorn sapling with a crooked root-knot for the grip, ornamented with a picturesque array of wart-like lumps.

Every country on earth has an indigenous cane. An artistically carved olive wood cane, with a camel's head for a handle, comes from Turkey. France has a cane of woven grass; Scotland, a thistle cane; Switzerland, a horn-and-hoof cane representing an Alpine goat; the West Indies, a lemon wood cane; the Philippines, a cane made of bones; and Cuba, a cane of shark's vertebrae. In certain remote regions of Africa, the tribal chieftain's cane is made with a large ball for the grip. Legend has it that the ball represents the most the chieftain can get into his mouth; hence, the bigger the ball the greater the chieftain. In the United States there are canes with handles that represent the faces of well-known persons; for example, Will Rogers, Franklin D. Roosevelt, William Jennings Bryan, William McKinley, and even William Shakespeare.

Robert Ripley, the famous creator of "Believe It or Not," was one of the best-known collectors of canes. While his personal collection was not the largest in the world, it contained many rare and exotic items. The Ripley collection included a cane made from the rib of a whale; a violin cane, probably the most unusual of all, which contained a playable violin with a bow; and a "blackout" cane, which had been used in England by Winston Churchill.

The story of the most famous cane associated with the medical profession appears in a book called "The Gold Headed Cane." This cane was the companion of five famous English doctors, and was transferred from one to the other. The widow of the fifth owner presented the cane to the Royal College of Physicians in London, where it is preserved. It is a Malacca stick with a crossbar for its handle, and it is decorated with the coats of arms of the doctors who owned it.

American doctors in the past have had a professional rather than a personal relationship to walking canes. Many doctors in the last century kept a collection of canes in their offices for the purpose of circulating them among patients who required them. During the latter decades of the 19th century there lived, in a small village in Kentucky, a bearded, old-fashioned physician known in the community as "cane-toting Doc Smith." This appellation had been bestowed on him because he always had handy, in his small office as well as in his one-horse buggy, a supply of courtesy canes, which were loaned to patients requiring their aid during convalescence.

There is also a story about a physician who lived in a midwestern city and had a great many talents, painting pictures, writing poetry, and playing several musical instruments. His very special hobby, however, eccentric though it may have been, was to wait for a heavy snow and then sally forth with his cane, drawing pictures in the snow for the amusement of the neighborhood children. There was another doctor who was a self-serving apothecary. He carried a cane with a gold head which contained a vial of ammonia and camphor, to be used in reviving women who fainted in public places.

Today's cane-minded doctor should find a new vista opening up when he considers the manifold uses to which a walking cane can be put. As its devotees know, the walking cane can be carried for sheer amusement rather than for actual support. For those who like to walk, the cane is a well-mannered companion, never talking back, but permitting its owner to entertain his hands as he reflects on the happenings of a busy medical day.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Potassium, Digitalis and the Heart. C. Fisch, E. F. Steinmetz, A. F. Fasola and B. L. Martz. J. Indiana M. A. 52:192-197 (Feb.) 1959 [Indianapolis].

The major effects of oral or intravenous infusion of potassium on the electrocardiogram are mentioned. In the presence of normal renal function a human being cannot ingest sufficient amounts of potassium to produce significant electrocardiographic changes because of gastric irritation. However, studies in animals show that acute loading with 1 mEq. per kilogram of body weight by the oral route may elevate serum potassium to toxic levels. The excretion of potassium after acute loading has been investigated under various states of renal function. In congestive heart failure a negative potassium balance usually exists. The effect of the oral administration of large amounts of potassium was investigated in patients with compensated heart disease and in those with heart disease with congestive failure. Those with heart failure showed poorest tolerance for potassium, with the highest rise of plasma level and a parallel low renal excretion of the cation. Normal subjects excreted most of the administered ion within 3 hours, and their plasma levels were low.

Chemical analysis of myocardial tissue in congestive failure revealed an absolute diminution of intracellular potassium with a concomitant rise in intracellular sodium. Differential analysis of the right and left ventricles showed that this decrease is more pronounced in the chamber "primarily" responsible for the congestive failure. Digitalis tends to reverse this process. It maintains the intracellular to extracellular ratio of potassium by aiding in the transport of potassium into the cell, or preventing the egress of this cation from the cell. On the other hand, it is pretty well agreed that toxic doses of digitalis result in egress of potassium from the cell. As potassium is extracted, symptoms and electrocardiographic changes suggesting digitalis intoxication become evident, and these can be reversed by administering potassium salts. In clinical practice the problem of potassium balance is further complicated by anoxia and by the use of acidifying agents, carbonic anhydrase inhibitors, mercurial diuretics, and sodium and potassium removing resins. The occurrence of the signs and symptoms of digitalis intoxication, after the use of mercurial diuretics, has been attributed to mobilization of digitalis from the edema fluid, but more recent studies have shown that digitalis intoxication occurs after diuresis during which significant amounts of potassium are lost.

During the past 3 years the authors made a systematic study of the effect of potassium on cardiac arrhythmias associated with digitalis therapy. Their studies not only failed to demonstrate any lasting benefit of potassium in the treatment of ventricular ectopic rhythms accompanying digitalis therapy but also suggested that potassium may actually potentiate digitalis toxicity. They feel that the observed effect of potassium on ectopic ventricular beats, with parallel depression of atrioventricular conduction, is best explained by the known nonspecific depressing effect of potassium on the myocardium. They emphasize, however, that their results to date apply only to intravenous injections of potassium of 5 mEq. per kilogram, at a rate of 0.5 to 1.0 mEq. per minute, to patients who have, as best as can be determined, normal total body potassium.

Unilateral Peripheral Facial (Bell's) Paralysis in Infectious Mononucleosis (Differential Diagnosis of Pfeiffer's Disease). L. Amann. München. med. Wchnschr. 101:270-271 (Feb. 13) 1959 (In German) [Munich, Germany].

Infectious mononucleosis, known also as Pfeiffer's disease, is probably a disease of the reticuloendothelial system of virus origin. This explains the extreme multiformity of its symptomatology, referred to by some as the "amazing masquerade" and by others as its "protean nature." On the basis of the history of a 5-year-old boy, the author shows that the neurological manifestations of infectious mononucleosis may cause it to be mistaken for poliomyelitis. Two days before this boy was hospitalized, his mother had noted that the angle of his mouth was drooping. Severe perspiration was observed during the night, and on the following

---

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1950 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

day swelling of the cervical lymph nodes was noted. The otolaryngologist who was consulted suspected poliomyelitis and advised hospitalization.

When the boy was examined on admission, it was found that all 3 branches of the facial nerve were paretic, but otherwise there were no neurological symptoms. The tonsils were somewhat red but not coated. Painful lymph nodes, the size of plum pits, could be palpated in the submandibular and submental regions and along the sternocleidomastoid muscles. The spleen was noticeably enlarged and tense, and the liver slightly protruded beyond the costal arch. The temperature was slightly above normal for the first 4 days but then became normal. The sedimentation rate of the erythrocytes was noticeably accelerated. The blood picture with the large number of monocytic cells was pathognomonic for infectious mononucleosis. The weakly positive Hanganatziu-Deicher reaction, the cervical lymphomas, and the swelling of the spleen corroborated this diagnosis. The author feels that, since there was no indication of any other etiology, the peripheral facial paresis must be ascribed to the infectious mononucleosis.

There is a considerable literature on neurological manifestations of infectious mononucleosis. Estimates of their incidence vary from about 1 to 10%. They assume many forms, such as serous meningitis, meningoencephalitis, central or peripheral paresis, sensory disturbances, convulsions, polyradiculitis, neuritis, and psychotic changes. Together with other neurological symptoms, central or peripheral paresis of the facial nerve has been observed in about 14% of the patients with neurological complications, but isolated facial paresis has so far been reported in only 4 other patients with infectious mononucleosis. The time of occurrence of the neurological symptoms has varied between the 1st and the 40th day of the disease. It has been suggested that corticotropin or cortisone might favor the development of neurological complications in infectious mononucleosis.

Thyroiditis and Struma Lymphomatosa (Hashimoto). L. E. Christensen. Ugesk. læger 121:129-131 (Jan. 22) 1959 (In Danish) [Copenhagen].

Some of the less common thyroid affections, including light cases of acute, nonsuppurative thyroiditis and particularly lymphomatous struma, will cause diagnostic difficulties. In acute thyroiditis the most important and most constant finding is the low absorption of radioiodine (I^{131}) in the gland. It is thought that in the 2 cases of acute thyroiditis reported the increased protein-bound iodine (PBI) inhibited the production of thyrotropic hormone and glandular absorption of iodine. Both patients reacted with a powerful increase in the absorption of I^{131} after stimulation of the thyroid gland with thyrotropic hormone (TSH). In the first case treatment with cortisone in usual dosage had a striking effect; in the second case spontaneous recovery occurred. In the third case described, in a patient with Hashimoto's struma, a myxedematous condition was about to develop. The destruction of glandular tissue had been so profound that hormone production had not been adequate. The remaining functioning tissue had presumably worked with maximum speed and been strongly stimulated by thyrotropin, as shown by the increased PBI^{131}.

Histologically, Hashimoto's struma is characterized by the supplanting of the normal thyroid tissue by lymphoid follicles with prominent germ centers; there is also diffuse infiltration of plasma cells with fibrosis. The affection starts with gradual enlargement of the thyroid gland. In many cases there are beginning symptoms of hypothyreosis. The sedimentation reaction is always increased. A positive precipitin test is of great diagnostic value, but the test is not specific for lymphoid struma and is positive in some cases of thyroid carcinoma. A constant and significant finding in Hashimoto's struma is that stimulation with thyrotropic hormone does not lead to increased absorption of I^{131} in the gland. In cancer of the thyroid there will, as a rule, be increased absorption of I^{131} after TSH. In thyroiditis there is often increased PBI^{127} but only insignificant absorption of I^{131} in the thyroid gland. In Hashimoto's disease the PBI^{127} is low and the PBI^{131} high.

Milkborne Streptococcal Sore Throat: A Study of 835 Cases. P. J. Taylor and M. A. McDonald. Lancet 1:330-333 (Feb. 14) 1959 [London].

In 3 similar epidemics at Akrotiri, a large Royal Air Force station in Cyprus, in the summer of 1957, 835 patients with tonsillitis or pharyngitis were admitted to hospital. The 3 waves began on May 12, May 26, and Aug. 3, and all showed the explosive start suggesting a food-borne infection. All patients were living-in airmen eating in one mess. Breakfasts were the only meals which all the patients had attended, and milk in tea or on cereals was the only common food. By the third epidemic it was realized that the 3 outbreaks had appeared during the weekends after the fortnightly pay parades. All milk consumed at Akrotiri was tinned milk diluted with water. The kitchen regulations stipulated that milk should not be prepared until just before breakfast at 5:30 a. m. and that it should be kept in covered containers. But 2 cooks admitted that on these fortnightly pay nights, because of pressure of work later in the night, they often made up the milk at midnight and that it was often sampled thereafter. The mess staff had their throats swabbed on May 14, and this yielded 12 positive cultures of group A streptococci out of 64 persons. These findings seem compatible with milk being the vehicle of infection.

The illnesses began abruptly with malaise or sore throat, and almost all patients were admitted within 24 hours. Considerable injection of the throat was the rule, with a variable amount of edema, and purulent exudates were seen in all with intact tonsils. Tender cervical lymph nodes were also present. The characteristic punctate erythema of scarlatina, usually only moderate in severity, was observed in 120 of the 835 patients. Of the 751 patients whose throats were swabbed on admission, 432 were found to carry group A Streptococcus pyogenes. All 12 representative subcultures from the first 2 waves sent to the Streptococcic Reference Laboratory belong to Griffiths type 5/12/27, while the 7 subcultures from the third epidemic were found to belong to either Lancefield group A or group G.

While it was not possible to compare the results of the different methods of treatment in all outbreaks, some assessment could be made of the effect of previous tonsillectomy; the results suggest that the operation is associated with a lowered susceptibity to infection, but once the illness is established, the individuals fare no better than their intact brethren, as judged by the height and duration of fever. Bacteriologically, however, there is a difference between the 2 groups, since more patients with intact tonsils had positive throat cultures than those without tonsils. In all 3 waves 19.6% of patients had a positive throat swab when they had recovered clinically. The breakdown of the carrier rate reveals noteworthy differences: penicillin (99 cases) carrier rate, 1%; Sulfatriad (336), 14%; aspirin (383), 24%. The final carrier rate two weeks after discharge from hospital for all patients was 4.7%.

Food-borne epidemics of streptococcic tonsillitis differ from the more common air-borne outbreaks by their abrupt onset, sudden termination, and low complication rate. It has been suggested that these characteristics are produced by a massive infection with a relatively avirulent organism.

Coexisting Primary Lung Carcinoma and Pulmonary Tuberculosis: A Report of Fifteen Cases Discovered Through a Chest Clinic and Hospital.

F. C. White, F. Beck and D. V. Pecora. Am. Rev. Tuberc. 79:134-141 (Feb.) 1959 [New York].

Fifteen men, between the ages of 42 and gh
years, in whom pulmonary tuberculosis coe sev-
with carcinoma of the lung, were observed This
Ray Brook State Tuberculosis Hospital i ll the
Brook, N. Y. All the patients had smok
adolescence, and 5 had consumed mo a com-
cigarettes daily for many years. T crocythemia
the tuberculosis, according to the their relativ
ards of the National Tuberculosis Association, was minimal in 4 of the 15 patients, moderately advanced in 6, and far-advanced in 4. Neoplastic and tuberculous diseases were so intermixed in one patient that the extent of the tuberculous disease could not be determined. The site of the origin of the primary carcinoma was ascertained in 14 of the 15 patients. The right upper lobe bronchus was involved in 8 patients; the right lower lobe in 1, the left upper lobe in 1, the left lower lobe in 3, and the left main bronchus in 1. A review of serial chest roentgenograms and pathological data revealed that in 7 patients the carcinoma arose in an area in which no evidence of previous tuberculosis was apparent. Carcinoma and tuberculosis occupied the same general area in the lung in 6 patients. Carcinoma was diagnosed in one patient with a negative tuberculin reaction; subsequently, the tuberculin reaction became positive, and tubercle bacilli were found in the sputum. The primary site of origin of a diffuse alveolar-cell carcinoma was not found in the remaining patient.

In 7 patients the earliest roentgenographic evidence of primary carcinoma of the lung appeared as a circumscribed nodular homogeneous shadow in the middle lung zone in the region of the second or third bronchial division. Unilateral enlargement of the hilus was the presenting roentgenographic sign in 3 patients and was associated with relative airlessness of a segment of the lung in 2 of these. The first abnormality in the chest roentgenogram of one patient was a spontaneous pneumothorax with an 80% collapse of the lung. Increased radiopacity of a portion of the lung due to relative airlessness without hilar enlargement was seen initially in 2 patients. In the remaining 2 patients carcinoma was not recognized roentgenographically even in retrospect. In most patients the shadows in the chest roentgenogram, which in retrospect were found to be due to carcinoma, increased in size rapidly over a period of sever months. In one patient, however, the
chan erature took place gradually over a numb
of or's labora changes were entirely ycemia
to its an accelerat course of the -pituitary
ood-sugar-raising hormon roentg rease in the
depth and duration of the hypoglycemic state intensifies the stimulus on the secretory activity of the adrenal-pituitary system; as a consequence the action of the blood-sugar-raising hormones can cancel out the action of injected insulin and tip the balance in favor of the former. The result is a sharp rise in the glycemic level, despite the presence of active insulin, and exorbitant hyperglycemia and glycosuria after alimentation in this condition. When hyperglycemia due to excess insulin action is countered by administration of in-
d doses of insulin, under the assumption that
lycemia can only result from a deficient in-

[illegible] Fenisecarum. [illegible] Canad. M. A. J. 80: [illegible]

[illegible] the entity of "farmer's [illegible] fenisecarum. This ap- [illegible] condition in areas, such [illegible] Valley of Nova Scotia, where so [illegible] farmers, raising cattle, working [illegible] sometimes moldy hay, or thresh- [illegible] like most fungous diseases, the in- [illegible] does not appear to invade the lung. [illegible] clinical features of farmer's lung is its [illegible] nature. Its onset is usually acute, and [illegible] may be quite ill with severe dyspnea but [illegible] without bronchospasm. The patients have [illegible] fever, and the blood sedimentation rate may be increased. There is frequently marked cough but very scanty sputum. Exacerbations occur on further contact with the source of the causative organism, but once the patient is removed from contact with the grain and its contaminating spores, improvement is rapid. Rarely does the disease progress to the development of cyanosis or emaciation, but these can occur, and the outcome can be fatal. The roentgenologic picture may simulate miliary tuberculosis or other diseases causing disseminated fine nodular or fibrous shadows in both lungs, which render the diagnosis difficult. These manifestations of allergic origin are based on a hypersensitivity to spores which are found in moldy hay or grain. It is, therefore, suggested that some acute pulmonary illnesses which occur in farmers may on occasion be due to a mold spore pneumoconiosis or farmer's lung.

Treatment of Autoimmune Hemolytic Anemia with Prednisone: Clinical and Serologic Findings. M. Martelli, R. Martinez and F. Caronia. Riforma med. 73:128-133 (Jan. 31) 1959 (In Itali[illegible] Naples].

Thyroi[illegible]itial intensive treatment [illegible]matosa (Has[illegible]ne, moto). L. [illegible]f a monthly do[illegible] læger 121:129-[illegible] (Jan. 22) 1959 (Gm., [illegible]n) [Copenhagen].

Some of the less common thyroid affections, including light cases of acute, nonsuppurative thyroiditis and particularly lymphomatous struma,

tion of previously inffective blood transfusion produced hematological and general improvement in this patient. This management was continued in some degree after the patient's discharge.

Serologic investigations of the 6 patients revealed dissimilar and delayed responses. The direct Coombs test became negative in 4 patients; in 2 of them it was accompanied by diminution in the titer of serum agglutinins. The titer of serum antibodies diminished significantly in one patient with a persistent positive response to the direct Coombs test. The patients were followed up and were found to be well for a period of 12 to 20 months after discharge. Prednisone has thus been demonstrated to exert a beneficial, but not curative, action in patients with autoimmune hemolytic anemia.

Thrombophlebitis of the Superficial and Deep Veins Treated with Phenylbutazone (Butazolidin). E. J. Orbach. J. Internat. Coll. Surgeons 31:165-168 (Feb.) 1959 [Chicago].

The treatment of thrombophlebitis has been greatly influenced not only by anticoagulant therapy but also by the observation in 1954, by Swiss and American authors, that the perivascular inflammation associated with acute superficial thrombophlebitis could be rapidly resolved by the use of the anti-inflammatory agent, phenylbutazone. Since then a number of investigators have confirmed the impression that phenylbutazone is an extremely effective agent in treating thrombophlebitis. The studies presented here aimed to ascertain the value of the use of phenylbutazone, together with early ambulation and consistent use of compression bandages, in the treatment of thrombophlebitis affecting either superficial or deep veins. Twenty-two patients with acute thrombophlebitis were selected for treatment with phenylbutazone. In 12 of the patients the disorder affected only superficial veins of the leg or thigh; deep veins were affected in the other 10, with superficial veins also involved in 1 case. The patients ranged in age from 33 to 78 years, most of them being between 50 and 70. Although none had a history of previous embolism, several had had episodes of thrombophlebitis. Symptoms of the current disorder had been present for less than [illegible] weeks before phenylbutazone therapy was ini[illegible]ted. The phlebitis occurred postoperatively in
Th[illegible]tients, after injection of sclerosing agents in 4,
not [illegible] mechanical trauma in 1 (diabetic) patient,
5:30 a[illegible]as of obscure origin or associated with
contain[illegible]ities in the rest.
fortnig[illegible]ylbutazone was administered orally to 16
later in [illegible]nd intramuscularly to 6. The usual oral
at midnight [illegible] mg. daily, given in divided doses,
after. The me[illegible] days. When administration was
on May 14, and [illegible]hat time, the dose was fre-

quently reduced to 200 mg. daily. Oral phenylbutazone therapy was never continued longer than a week, and the total amount administered did not exceed 2.1 Gm. Used intramuscularly, a single injection of 600 mg. of phenylbutazone was generally sufficient, since the drug is absorbed slowly from intramuscular depots. Compression bandages were used to reduce the initial edema and to prevent further swelling, and early ambulation was encouraged. In several cases of superficial thrombophlebitis the vein was incised and the clotted or stagnated blood removed. Because patients in this study were to be given phenylbutazone for no longer than one week, hematological studies were not considered essential.

Signs of acute inflammation subsided rapidly. A second course of phenylbutazone was successful in one of 2 patients in whom the phlebitis recurred. In the other patient a second course was not attempted. No toxic or other undesirable effects from phenylbutazone therapy were observed in any of the patients, and the author believes that this agent will prove helpful in the management of thrombophlebitis involving either superficial or deep veins.

Further Observations on the Clinical, Morphologic, Hematochemical and Electrophoretic Aspects of Microdrepanocytic Disease. R. G. de Benedetti, F. di Tullio and P. Strigini. *Haematologica* 43: 1109-1122 (no. 11) 1958 (In Italian) [Pavia, Italy].

Microdrepanocytic anemia was discovered in 2 brothers; one was 2 years and 5 months old, and the other was 5 years and 6 months old. Blood tests were given to the whole family of the patients, and microcythemia and sickle-cell anemia were found as hereditary diseases. Three of the 4 great-grandparents of the children were of Sicilian origin; the family belonged to blood group B. Microcythemia, which was found in the father and in the elder brother of the 2 aforementioned patients, was characterized by a reduced volume and diameter of the erythrocytes and by an increase in the A_2 fraction in electrophoresis. Sickle-cell anemia, which was found in the mother and in a maternal uncle of the 2 children, was evidenced by the separation of the hemoglobin S band in the electrophoresis and by the "sickling" phenomenon. The "sickling" phenomenon was discovered by making tests on fresh blood and by provoking anoxia in vivo. For the latter test a current of carbon dioxide was bubbled through the blood, and then the blood was stored for several hours in a humid chamber at 37 C. This latter test showed "sickling" in practically all the elements.

The 2 children reported on presented a combination of the symptoms of both microcythemia and sickle-cell anemia present in their relatives plus abdominal pain. In one child a slight swelling appeared on the dorsum of the hand, but he had no fever, and the authors believe that the swelling was caused by changes in the circulation of the sickle-shaped erythrocytes. In the other child the liver was found to be enlarged and painful; bilirubinemia was high; the child was rather pale in color; and jaundice was present in the scleras.

Exacerbation of Diabetes by Excess Insulin Action. M. Somogyi. Am. J. Med. 26:169-191 (Feb.) 1959 [New York].

Detailed laboratory data, gathered in closely controlled observations and experiments on 4 men, between the ages of 23 and 36 years, and a 24-year-old woman with severe diabetes, revealed complete lack of parallelism between the amount of insulin injected and the amount of carbohydrates utilized; even when both diet and insulin dosage were kept constant, glycosuria varied over wide ranges, and the blood sugar oscillated between very low and very high levels. The laboratory records of patients who were treated with substantial doses of insulin revealed a consistent pattern of periodic ebb and tide in the fluctuations of both the glycosuria and the glycemic level, and disclosed the fact that the high tides consistently occurred in the wake of hypoglycemic reactions, even after asymptomatic, mild degrees of hypoglycemia. Thus, a clear-cut cause-and-effect relationship unfolds itself between hypoglycemia and the ensuing upsurge of hyperglycemia, and one is confronted with the paradoxical fact that excess insulin action can produce hyperglycemia. It can be stated that, barring other physiological and emotional stresses, conspicuous fluctuations in glycosuria are unmistakable indicators of excess insulin action.

The impairment of carbohydrate tolerance as a sequel of hypoglycemia is readily explained on the basis of experimental evidence available in the literature and supplemented by studies in the author's laboratory, which show that hypoglycemia elicits an accelerated release of adrenal-pituitary blood-sugar-raising hormones. Increase in the depth and duration of the hypoglycemic state intensifies the stimulus on the secretory activity of the adrenal-pituitary system; as a consequence the action of the blood-sugar-raising hormones can cancel out the action of injected insulin and tip the balance in favor of the former. The result is a sharp rise in the glycemic level, despite the presence of active insulin, and exorbitant hyperglycemia and glycosuria after alimentation in this condition. When hyperglycemia due to excess insulin action is countered by administration of increased doses of insulin, under the assumption that hyperglycemia can only result from a deficient insulin supply, the result is exacerbation of the diabetic syndrome, manifested in extreme fluctuations of glycosuria, with mounting peaks and ketonuria; at the same time, recurrent hypoglycemic reactions increase in severity.

It is evident that in insulin therapy avoidance of hypoglycemia, even of mild, asymptomatic degrees, is no less important than the control of excessive hyperglycemia and glycosuria. Application of this precept makes it possible to forestall the development of severe states of diabetes, and to restore patients with severe diabetes to a status of mild diabetes that can be satisfactorily managed with small doses of insulin or, not infrequently, without insulin. One should adjust the insulin dosage and diet not so much to abolish glycosuria but to achieve maximal glucose utilization per unit of insulin administered. This can often be achieved, even in the "unmanageable" patients, by slow reduction in insulin dosage, with proper distribution in relation to the adjusted diet.

The Problem of the Intrahepatic White Bile. M. L. Leger, P. Rambert, J. Canivet and others. Presse méd. 67:168-171 (Jan. 28) 1959 (In French) [Paris].

In addition to the known occasional occurrence of white bile in the common bile duct, there are also cases in which white bile has been found within the liver, which poses a much more complex physiopathological problem. Four patients are presented in whom the white bile within the liver was demonstrated by means of transparietal hepatic puncture and insertion of a Polythene tube at the site of the needle. All the patients had obstructive jaundice of from 50 days' to 3 months' duration, due to a cancerous tumor on the head of the pancreas. A more detailed description is given of a 5th patient who had severe retention jaundice of 10 months' duration due to complete obstruction of the biliary ducts by alveolar echinococcosis of the liver. Cholangiography revealed greatly dilated intrahepatic ducts in all the patients. It was interesting that bile flow and bile pigment were rapidly restored after drainage. The initially white bile of the 5th patient was rapidly followed by darker bile, and, within 15 hours after drainage had begun, the bilirubin content was far above normal. These facts suggest that the intrahepatic white bile cannot be attributed to a parenchymatous functional disorder of bile formation, but rather to an excretory mechanical disorder, although the hepatic cells were affected.

Acholia, as the word is used by the authors, was not manifested by these patients, because biligenesis existed; the secretory activity that produces bile was present; the drainage of the intrahepatic ducts alone was sufficient to permit excretion of bile with normal bilirubin and cholesterol levels. The significant physiological role of Disse's spaces in this phenomenon is stressed. In opposition to the generally accepted view, the authors do not believe that the presence of white bile necessarily implies an unfavorable prognosis. It is rather the frequently malignant nature of the obstruction, inhibiting the excretion of bile, which is responsible for the fatal outcome.

The Time of Appearance of Bromsulphalein (BST) in the Bile: Observations in the Diseases of the Biliary Tract. J. Latvalahti and O. Alfthan. Ann. med. int. Fenniae 47:175-182 (no. 4) 1958 (In English) [Helsinki].

The authors performed the Bromsulphalein test on 88 patients, by means of duodenal intubation, to determine the time of appearance of Bromsulphalein (BST) in the bile. Of the 88 patients, 21 were chosen as a contra test group; no clinical symptoms or laboratory tests pointed to bile or liver disease in these patients. All these contratest patients showed a normal Bromsulphalein retention in the blood, and the BST values obtained ranged from 15 to 25 minutes. Of the 67 selected patients with various hepatobiliary diseases, 17 presented a BST of 25 minutes or less. Protracted times were observed in the remaining 50 patients. Among the 50 patients, no mechanical reason for the lengthened BST was discovered in 27 who had hepatobiliary diseases. The anatomic reason for the protracted BST in 13 patients was choledocholithiasis; in 5, obstructive biliary carcinoma; in 4, biliary cirrhosis; and in 1, ductus cysticus remanens. The determination of the BST seems to be serviceable as an additional examination in diseases of the biliary tract. The test is easy to perform. Although the simple finding of a lengthened BST must be treated with reserve if there is nothing else indicative of biliary disease, it may be emphasized that protracted times were not observed in patients who had no hepatobiliary diseases. A shortened BST, though, does not exclude with certainty a relative obstruction in the biliary system.

SURGERY

Traumatic Rupture of the Normal Spleen. W. W. Francis and J. Benavides. Rhode Island M. J. 42:102-104 (Feb.) 1959 [Providence].

Thirty patients with traumatic rupture of the normal spleen were admitted to the Rhode Island Hospital, Providence, during the period from January, 1946, to August, 1958. Seventeen of the patients were less than 20 years of age; 22 were male and 8 female. Only 6 of the patients sustained their injury in automobile accidents. Twenty-eight of the patients had nonpenetrating and 2 had penetrating traumas. Rupture occurring within 48 hours after the injury is arbitrarily defined as primary; if it occurs later, it is called the delayed type. In this series, 5 ruptures were of the delayed type. Eighteen patients had associated injuries; rib fractures, the commonest, were present in 6 patients. Renal injuries existed in 3 patients, a lower incidence than in other reports on splenic rupture.

Abdominal pain associated with tenderness and spasm involving primarily the left upper quadrant was present in a high percentage of the cases in this series. Sixteen patients complained of shoulder pain, while 22 patients showed some evidence of shock. In only one patient was a mass palpable. A high percentage of the patients had a white blood cell count over 10,000. Eight patients showed roentgenologic signs suggestive of ruptured spleen, such as elevation of the left leaf of the diaphragm, obliteration of the splenic shadow with serration of the greater curvature of the stomach, or left upper quadrant mass with or without displacement of abdominal organs. Diagnostic peritoneal taps were done in 5 of the patients and yielded blood in 3. The authors present the history of a patient in whom diagnostic peritoneal tapping clarified an obscure picture and allowed immediate, lifesaving surgery. The technique of this procedure is described.

There is little doubt that splenectomy is the treatment of choice for rupture of the spleen. This is borne out in this series by the fact that the only 2 deaths occurred in patients not operated on. Of the 28 patients treated surgically, 25 had splenectomies, and 3 merely had repair of the splenic injury. Although these 3 patients recovered, this procedure is not recommended. Thirteen of the operations were carried out through left-sided rectus incisions, while 11 were done through subcostal incisions. Various incisions were used in the other 4 cases.

Operative Technique in Funnel Chest: Experience in 81 Cases. V. Paltia, K. V. Parkkulainen, M. Sulamaa and G. R. Wallgren. Acta chir. scandinav. 116:90-98 (no. 2) 1958-1959 (In English) [Stockholm].

After citing a number of surgical techniques suggested by others for funnel chest, the authors say that since 1951 they treated a total of 81 patients for funnel chest. In the first 11 of these patients they applied a modification of Ravitch's or Wahren's technique. Postoperative stabilization of the sternum was by no means satisfactory in all cases, and respiration produced paradoxical motion on either side of the totally freed sternum.

The remaining 70 patients have been operated on since 1954 according to the authors' own method, the main features of which were transverse incision, freeing of the origin of the pectoral muscles, subperichondral resection of the deformed costal cartilages, division of the xiphisternal joint, stripping of the posterior surface of the sternum, and stabilization by means of a metal strut introduced through the sternum with its ends resting upon the costal stumps. The strut was removed after 3 months. There were no deaths. Complications were pneumothorax in 11 and wound infection in 7 of the 70 patients. Clinically the result, as estimated either at the removal of the strut or later, was considered good or satisfactory in more than 90% of the cases. Cosmetically the result was considered good in 51 cases, satisfactory in 10, and poor in 2. In the cases with a poor cosmetic result the strut had been removed 30 and 40 days, respectively, after operation because it had shifted. There were altogether 10 cases in which the strut was removed earlier because it had shifted. The authors stress the simplicity of their method, its freedom from risk, and the good results obtained.

Controlled Studies on the Efficacy of Bilateral Internal Mammary Artery Ligation in Patients with Angina Pectoris. R. E. Fremont, R. Klopstock and P. Glass. Angiology 10:20-27 (Feb.) 1959 [Baltimore].

Eight patients, between the ages of 32 and 66 years, who had severe coronary artery disease associated with distressing attacks of anginal pain and who failed to respond to medical therapy, underwent ligation of both internal mammary arteries in the second intercostal space (B. I. M. A. L.). In 4 additional patients, between the ages of 33 and 39 years, with angina pectoris, a sham procedure and serial exercise electrocardiogram and ballistocardiogram tests were performed. The sham procedure consisted of bilateral skin incisions, the localization of the internal mammary arteries, and the encirclement of these vessels by loose ligation. This sham operation was followed by the actual B. I. M. A. L. in 3 patients after 2 to 6 weeks. The latter operation was omitted in the 4th patient because he sustained in the interval period a mild myocardial infarction.

Two of the group of 8 patients died, one 4 hours after the well-tolerated operation and the other 11 days after the operation. The 6 surviving patients showed prompt symptomatic relief of variable duration, which ranged from 1 week to 4 months. In none of these patients was there any improvement of the rest electrocardiograms or ballistocardiograms. Of the 3 patients who underwent both sham procedures and B. I. M. A. L., one noted prompt relief after the sham procedure, with reduction of the daily need of glyceryl trinitrate; 6 weeks later his use of glyceryl trinitrate tablets had increased again, and after the actual B. I. M. A. L. there was again prompt relief for about 10 days, but within 2 months he was again using 10 tablets of glyceryl trinitrate and again had occasional decubital anginal pain. The 2 other patients in this group failed to show any objective and subjective improvement after the sham procedure; they obtained subjective improvement after the B. I. M. A. L. lasting 8 to 10 months.

The results of these pilot studies revealed numerous pitfalls in the evaluation of patients before and after surgical treatment both as regards symptoms and, to a less extent, objective tests. B. I. M. A. L., like all other types of coronary surgery, has a considerable psychological component which is responsible for rapid subjective improvement in most patients, regardless of the severity of the disease. Prolonged subjective improvement was noted only in those patients who had a mild form of the disease. Objective improvement, as manifested by improved or normalized electrocardiographic response to exercise, is similarly limited to patients with the mildest forms of the disease. The use of the B. I. M. A. L. for the treatment of coronary disease requires further careful study based on a large number of patients and employing objective data. These should include sham procedures and exercise electrocardiography.

Short-Term and Long-Term Follow-up of Unoperated Patients with Certain Varieties of Acute Abdominal Diseases During the Past Decade: Patients from 60 to 85 Years of Age and Those Under 60. C. Parenti. Chir. ital. 10:622-647 (no. 6) 1958 (In Italian) [Milan, Italy].

A follow-up study was carried out by calling on 137 patients at home shortly, or at a longer interval, after their discharge from the hospital. All were patients who had certain varieties of acute abdominal diseases, but who had not undergone surgery either because they were poor risks or because they objected to surgery. Home visits enabled the author to distinguish deaths attributed directly to the previous acute abdominal disease from those related to other causes. The patients were divided into 2 groups; the older group included 109 persons between 60 and 85 years of age, and the younger group included 28 persons below 60.

Cholecystitis was present in 23 patients of the older group and in 11 patients of the younger group; acute cholecystitis associated with peritonitis, in 18 older patients and in 4 younger patients; acute appendicitis, in 14 older patients and in 1 younger patient; acute appendicitis associated with diffuse peritonitis, in 16 older patients; appendical abscess, in 35 older patients and in 9 younger patients; pelvic peritonitis, in 2 older patients and in 1 younger patient; sigmoiditis, in 1 older patient; and pancreatitis, in 2 younger patients. Patients with acute appendicitis associated with diffuse peritonitis, below 60 years of age, were operated on and, therefore, excluded from this investigation. Of the older group, 7 patients (43%) died of acute appendicitis associated with diffuse peritonitis, and 5 patients (14%) died of appendical abscess. No deaths took place among patients of the younger group.

This study discloses that a considerable decrease in deaths attributed to certain varieties of acute abdominal diseases has taken place during the past decade when antibiotics have been used. It also is interpreted to mean that emergency operation for acute cholecystitis is no longer justifiable.

Behavior of the Serum Glutamic Oxalacetic Transaminease (Aminopherase) Level in Relation to Surgical Operations. C. Andres. Chir. ital. 10:654-662 (no. 6) 1958 (In Italian) [Milan, Italy].

Values of serum glutamic oxalacetic transaminase (SGO-T) were recorded for about 50 patients before and after operation to investigate the relationship between surgical trauma and cellular metabolism. The ages of the patients ranged from 16 to 66 years. Four patients were operated on for inguinal hernia; 6, for chronic, subacute, or acute appendicitis; 13, for duodenal or gastric ulcer; 5, for gastric carcinoma; 7, for cholecystitis; and the remainder, for other disorders. The levels of SGO-T rose postoperatively in all instances, regardless of whether they had been within or above the physiological limits before the operation. The highest values were observed immediately after the operation; they were reduced to one-half or one-third in 24 hours, and were restored to normal levels within 2 or 3 days after the operation. There were no significant differences in these values when the operations were performed with the patients under either general or local anesthesia. The levels were higher in more traumatic and prolonged operations. The author concludes that there exists a certain relationship between the increased values of SGO-T and the postoperative shock. This investigation may not as yet have a practical application; in particular, it has no diagnostic value when undertaken within the immediate postoperative period.

Treatment of Paralysis of the Flexors of the Elbow. A. Segal, H. J. Seddon and D. M. Brooks. J. Bone & Joint Surg. 41B:44-50 (Feb.) 1959 [London].

This paper presents the results of operations carried out to restore active flexion of the elbow. Four operations were employed: (1) transplantation of the pectoralis major into biceps (*a*) according to Clark's (1946) method and (*b*) according to the Brooks-Seddon (1959) method; (2) transplantation of triceps into biceps; and (3) proximal transplantation of the common flexor and extensor origins—Steindler's operation. The authors studied 41 patients who had lost active elbow flexion, either from a traction lesion of the brachial plexus (20 patients) or after an attack of poliomyelitis (21 patients). The average period of postoperative observation was 4 years and 8 months, the shortest period being

10 months and the longest 11 years. Clark's transplantation was carried out in 17 patients, the Brooks-Seddon transplantation in 8, Steindler's transplantation in 13, and triceps transplantation in 3 patients. The results were graded objectively and subjectively.

As regards the objective results, Steindler's transplantation gave the best results, followed closely by Clark's pectoral transplantation, the other 2 types of transplantation being less satisfactory. However, because each method of operation has certain advantages and disadvantages, the results are further analyzed with regard to (1) the passive movement of the elbow, (2) active and passive supination, and (3) associated movements. The results were better when the extension of the elbow was limited; such limitation always occurs after Steindler's operation, but infrequently after pectoral transplantation.

The results of pectoral transplantation are good when there is no significant shoulder paralysis; if there is shoulder weakness, arthrodesis of the joint may be required to control medial rotation and adduction of the shoulder on flexion of the elbow. In brachial plexus lesions the results of pectoral transplantation may be marred by simultaneous contraction of the triceps. This can be overcome by transplanting triceps into the flexor apparatus. Triceps transplantation is rarely indicated because loss of active extension of the elbow is a grave disability.

Subjective results tended to be worse than objective results in brachial plexus lesions, because impairment of sensibility in the hand often limited the usefulness of the limb. In striking contrast the subjective results were, in general, far better than the objective in patients who had had poliomyelitis. In them the smallest gain can be of functional value.

Clinical Use of Vasectomy for Sterilization. B. B. Ohri and P. S. Jhaver. Indian J. Surg. 20:480-484 (Dec.) 1958 [Madras].

Five hundred forty-two vasectomies were performed on men, between the ages of 25 and 60 years, at the Medical College Hospital in Indore, India, between 1954 and 1957. Most of the men requested sterilization because they already had families of 4 to 17 children. Some of the men expected rejuvenation in addition. The first 50 patients were operated on by the standard two-incision technique with the aid of local anesthesia. In the other patients vasectomy was carried out through one central scrotal incision with an anteromedial approach to the vas deferens; this technique causes less pain, and only one small incision is required. Three hundred seventy-six patients were followed up by questionnaire to assess the clinical effects of the operation. Of the 376, 86 did not reply to the questionnaire, 278 were satisfied with the obtained results, and 12 were not. Six men complained of diminution of sexual capacity, 86 reported an increased sexual strength and desire, while 198 maintained that their sexual capacity remained as before. They were assured that their sexual capacity would not diminish but might increase.

Most of the patients obtained physical and sexual improvement and a great mental relief from the anxiety of further additions to the family. Bad effects reported were never due to the operation itself, but resulted from technical errors, namely, sepsis, injury to the blood vessels and nerves of the spermatic cord, or accidental cutting of structures other than the vas deferens. Vasectomy by a single scrotal incision is to be considered an ideal and safe procedure for control of conception and other purposes; it has no untoward effects on the physical, mental, and sexual faculties. Psychologically unstable men and those prejudiced to the operation should be advised not to undergo vasectomy.

Experiments on young rats, which were subjected to vasectomy and on which orchidectomy was performed within 2 weeks to 6 months after the first operation, revealed that vasectomy was followed by degeneration of the seminiferous tubules, but this degeneration was either incomplete or temporary. After vasectomy there was proliferation of the interstitial tissue of the testes.

The Short Leg in Poliomyelitis. A. H. C. Ratliff. J. Bone & Joint Surg. 41B:56-69 (Feb.) 1959 [London].

The author studied limb shortening after poliomyelitis in 225 children in whom paralysis was confined to one leg. The paralyzed leg became shorter than its fellow in 219 patients (97%). The discrepancy in leg length only once exceeded 3¼ in. Both the tibia and the femur were shorter than their fellows in 171 out of 184 patients studied (93%). In only one patient was the femur alone shortened. Three patterns were revealed in the progress of shortening; the progress was classified as rapid, when the discrepancy amounted to 2½ in. or more within 9 years or less of the onset of the disease; as slowly progressive, when the discrepancy increased slowly year by year, and amounted to 2 or 3 in. by the time the patient reached adult life; and as nonprogressive, when a discrepancy of up to 1½ in. was present 5 years after the onset of the disease, then remained constant until growth ceased. There was no evidence that a reduction in shortening ever occurs.

It proved impossible to predict the degree of shortening accurately. While, in general, it could be said that, the severer the paralysis, the greater the shortening, there were notable exceptions to this rule. No relationship could be found between the amount of shortening and the incidence of paralysis in any individual muscle group. There was no significant difference in leg shortening between those patients in whom the poliomyelitis had developed during the first 2 years of life and those in whom it had developed later. A cold, blue limb was not more likely to undergo severe shortening than one not so impaired. When paralysis was confined below the knee, shortening never exceeded 1¾ in.; when, however, muscles both below and above the knee were paralyzed, then shortening amounted to as much as 3½ in. The cause of leg shortening is unknown. Premature epiphysial fusion was observed in only 2 patients in this series.

Few references are to be found on the occurrence of increased growth in a leg paralyzed by poliomyelitis. In this study 7 patients with true lengthening were encountered. The discrepancy in all 7 was mild, being ¼ to ½ in. Six of these 7 patients had suffered a severe paralysis. Valgus deformity of the femoral neck sometimes occurs after poliomyelitis, and it was at first assumed that this might explain the increased length. Four of these patients, however, had femoral necks with only a mild degree of valgus deformity, and in only one could the lengthening be completely explained in this way. Four patients in whom the leg lengthening was detected during routine clinical examination had been treated on hip abduction splints. The significance of this observation, like the etiology of the lengthening itself, is obscure. The author concludes that lengthening of a paralyzed leg can occur during the first 2 years after the onset of the paralysis, but is always a temporary phase.

Treatment of Perforated Peptic Ulcer. C. A. Gherardi and F. Baldrati. J. Internat. Coll. Surgeons 31:154-160 (Feb.) 1959 [Chicago].

This report is based on observations on 181 patients with perforated peptic ulcers who were observed over the past 10 years; 13 (or about 7%) were women; the patients ranged in age from 14 to 84 years. Perforation was most frequent in the age group between 40 and 49 years, followed by those between 30 and 39 and 50 and 59. All but 6 of the patients were treated surgically. There were 20 deaths among the 175 patients operated on (11.4%). This rather high mortality rate was directly related to the length of time that elapsed between perforation and hospitalization and to the lack of adequate preoperative preparation, but the age factor also played a part. Simple closure of the perforation was the surgical method most frequently employed, and the authors regard this as the treatment of choice. Surgical therapy should be undertaken only after thorough preparation of the patient, and the immediate postoperative period should be planned with the same care and thoroughness.

Fifteen patients were subjected to an emergency subtotal gastrectomy. The authors believe that in the presence of large perforations, suspected neoplastic ulcers, bleeding ulcers, or pyloric stenosis, and provided that no more than 12 hours have elapsed since perforation, subtotal gastrectomy may be performed. Gastric aspiration and the administration of adequate amounts of fluids, electrolytes, and antibiotics are important in the preparation for operation. The postoperative treatment also must be carefully planned. Conservative treatment should be considered only when the patient can be kept under constant close observation and when there is no doubt that sealing off of the perforation is taking place. Surgical treatment shortens the course of the disease and prevents complications.

The Management of Venous Thrombosis and Pulmonary Embolism. W. F. Barker. Surgery 45:198-203 (Feb.) 1959 [St. Louis].

The author reports on 80 patients with deep venous thrombosis, 16 of whom also had a superficial saphenous thrombophlebitis, and 38 had pulmonary embolism during some part of their histories. Sixty-six of the 80 patients received anticoagulant therapy; 42 of the 66 were given heparin and 24 received bishydroxycoumarin (Dicumarol). There was a manifest recurrence of thrombophlebitis in 22 patients, 6 of whom had been given heparin, 11 Dicumarol, and 5 had not received anticoagulant therapy. In 6 patients the recurrence appeared while they received adequate anticoagulant therapy in the hospital (5 receiving Dicumarol and 1 heparin). In 11 patients recurrences appeared after intervals ranging from 2 days to 6 months after cessation of treatment of previous thrombophlebitic activity. Of the 38 patients with pulmonary embolism, 10 were not treated with anticoagulants, and all of them died. Twenty-eight were treated with anticoagulants; in only 6 of these was there no recurrence of embolism either while receiving anticoagulant therapy or after cessation of this therapy. Fatal pulmonary embolism occurred in 9 patients, 8 of whom were treated with heparin and 1 with Dicumarol. Ligation of major veins at a sufficiently high level was performed in 16 patients in an attempt to forestall anticipated pulmonary embolism; the vena cava was ligated in 4, the iliac vein in 3, and the femoral vein in 9 patients; the ligation was successful in 13 patients, but failed to prevent pulmonary embolism in 3 of the 9 patients with ligation of the femoral vein.

These data indicate a serious failure rate in the form of either recurrent venous thrombosis or of originally occurrent or recurrent pulmonary embolism in patients treated with anticoagulants. Heparin seemed to be more effective than Dicumarol in relieving the symptoms of venous thrombosis, but it was associated with a considerable number of fatal pulmonary embolisms in the presence of what appeared to be adequate therapy. Venous ligation, especially at the level of the vena cava, when tolerable by the patient and when supplemented by postoperative anticoagulant therapy, seemed to offer the safest course with minimal morbidity.

Twenty-five Years of Progress (III): Progress in Gallbladder and Biliary Tract Disease. W. H. Cole and W. Harridge. Am. J. Digest. Dis. 4:93-116 (Feb.) 1959 [New York].

For the past 2 or 3 decades, evidence has been accumulating indicating that cholecystitis is primarily an inflammation of chemical origin and that infection is superimposed on the inflammation. It has been shown that a change in the ratio of cholesterol to fatty acids or bile acids by absorption of the bile salts through the gallbladder wall is very important in the causation of gallstones, particularly the cholesterol type. Iodoalphionic acid (Priodax) and iodopanoic acid (Telepaque), administered orally, proved to be highly effective for visualizing the gallbladder on roentgenographic examination. Operative cholangiography has been useful in the discovery of stones in the common bile duct. Cholangiograms taken 2 weeks after choledochostomy proved to be a valuable aid in making sure no stones have been left at the time of the operation. Since air bubbles are, at times, difficult to distinguish from stones, the occurrence of air bubbles may be prevented by introduction of a tiny plastic catheter, filled with iodopyracet (Diodrast), downward into the T-tube, as far as it will go. If iodopyracet or sodium chloride solution is then injected, the air in the T-tube will be forced out. Intravenous cholangiography with the use of iodipamide (Cholografin) sodium, the first roentgenogram being taken 15 minutes after completion of the injection of the contrast medium and another 5 minutes later, has a definite advantage over postoperative cholangiography since the latter may introduce air into the common duct.

Some surgeons favor nonoperative treatment during an acute attack of cholecystitis and surgical treatment later after the acute inflammatory process has subsided. There is general agreement that, if the patient with acute cholecystitis is seen within 48 hours after onset of symptoms and the diagnosis appears quite accurate, prompt operation is advisable. Free perforation of the gallbladder into the peritoneal cavity with resultant bile peritonitis is a serious complication, resulting in death unless the corrective operation is performed within a few hours after the perforation has occurred. Immediate operation is usually advisable because of the danger of perforation if signs of impending gangrene of the gallbladder develop. The authors agree with those surgeons who feel that there should be a life expectancy of at least 7 or 8 years before advising cholecystectomy for asymptomatic cholelithiasis. Most of the strictures of the common bile duct are caused by trauma during cholecystectomy. Since treatment of these strictures is complicated and often associated with failure, the most important phase of therapy lies in prevention of this complication.

In patients with gallstones and pain located in the left part of the precordium, removal of the gallbladder containing gallstones is definitely indicated if there are no electrocardiographic changes and if there is no history of a coronary attack. Usually cholecystectomy for gallstones will eradicate the pain in such patients. Cholecystectomy for gallstones also may be indicated if the pain is not related to exercise, even though the electrocardiographic tracings are suggestive of coronary disease. Occasionally cholecystectomy will be indicated in patients with cholelithiasis if the electrocardiogram shows evidence of myocardial damage, and pain is present on exercise, provided that the cardiac status is well stabilized and there have been no attacks of coronary involvement for the past 3 to 6 months.

If a patient has had a cholecystectomy and is having residual symptoms, the two most likely causes of these symptoms are stone in the common bile duct and fibrosis of the sphincter of Oddi. If the common duct is explored for stones and there is an obstruction at the terminal end, an attempt should be made to pass a probe or scoop, 5 mm. in diameter, through the sphincter into the duodenum. If the sphincter is fibrosed and will not allow passage of the scoop or probe, the sphincter should be severed. It is actually desirable to cut the sphincter in 2 places to prevent reunion of the edges with reformation of the fibrosis. A T-tube should be inserted in the common duct after sphincterotomy, but should be removed early.

In a 5-year study conducted by the authors between 1948 and 1952, a zero mortality rate was noted for 169 patients, aged less than 60 years, undergoing cholecystectomy for cholelithiasis, and one death was noted among 54 patients over 60 years of age. In patients who have typical right upper quadrant pain associated with gallbladder disease, removal of the gallbladder will result in elimination of the symptoms in 95% of the cases. If cholecystectomy were performed for atypical symptoms, consisting perhaps of eructation, belching, and other symptoms of dyspepsia, results will be good in not more than 50 to 60%.

Early Clinical Manifestations of Cancer of the Colon and Rectum: A Statistical Study. H. L. Bockus, M. H. Kalser, Y. Mouhran and others. Dis. Colon & Rectum 2:58-68 (Jan.-Feb.) 1959 [Philadelphia].

A large proportion of cancers of the colon and rectum are curable if removed soon after the appearance of first symptoms. The over-all cure rate of colonic carcinoma exceeds that of cancer at any other site in the alimentary canal. The authors studied the early clinical manifestations of colonic and rectal cancer by reviewing the records of 418 patients with proved cases seen at the Graduate Hospital of the University of Pennsylvania, Philadelphia, from 1936 to 1958. There were 139 patients (33%) with cancer of the rectum, 209 (50%) with cancer of the right colon, and 70 (17%) with cancer of the left colon. Lesions occurring in the sigmoid as well as those in the midtransverse colon and distal thereto (excluding the rectum) are included under the designation "left colon." Before considering the early manifestations, the authors point out that colonic and rectal cancers are sometimes preceded by antecedent or precursor lesions. Such lesions were observed in 41 (9.8%) of the 418 patients. There were 4 patients with ulcerative colitis, 20 with a single polyp, 6 with multiple colonic polyposis, and 11 patients who had been operated on previously for cancer of the colon.

Abdominal pain or discomfort, blood in the stools, and change in bowel habits were the most significant early symptoms. Pain was the commonest early symptom, particularly in colonic cancers; it was somewhat less frequent in rectal cancers, but it existed in 78% of the entire series of 418 cases. Change in bowel habits was the second most common symptom; it occurred in 71% of rectal, 69% of left colonic, and 54% of right colonic neoplasms; it was the commonest first symptom in rectal neoplasms and was present in 67% of the entire series of cases. The third important early symptom was passage of gross blood in the stools; this occurred in 80% of rectal, 49% of left colonic, and 30% of right colonic lesions; it closely followed "change in bowel habits" as a first symptom in rectal neoplasms (37%) and occurred as a first symptom in 26% of lesions in the left colon (including the sigmoid).

While symptoms such as intestinal obstruction, anemia, weight loss, symptoms of metastasis, and palpable mass usually occur later in the course of colonic and rectal cancers, any of these manifestations of advanced growth may at times constitute the first clinical feature of the disease. Intestinal obstruction, usually a symptom of moderately advanced disease, was considered to be the significant presenting complaint in 16% of left colonic lesions, and in 11% of the entire series of 418 cases. Anemia was noted in 24% of all neoplasms and in 53% of right colonic lesions. Weight loss exceeding 10 lb. (4.5 kg.) was noted in 38% of the patients. Symptoms caused by metastasis were observed in 7% of the patients on admission. A palpable mass was recorded in 37% of the patients with colonic carcinomas (excluding rectum); it was present in 29% of left colonic lesions and in 69% of right colonic neoplasms.

Delay in diagnosis of over 6 months was attributable to the patients in 23% of the cases and to physicians in 28%. The average length of the delay was practically the same regardless of the location of the neoplasm. The over-all length of the delay in diagnosis was less in the group of patients seen after 1951 than in the group seen between 1936 and 1950.

Total Reconstruction of the External Ear. R. C. Tanzer. Plast. & Reconstruct. Surg. 23:1-15 (Jan.) 1959 [Baltimore].

After citing the principal difficulties in producing an acceptable substitute for a missing ear, the author discusses 4 concepts, some new and some modifications of the views of others, that have been evolved to create a technique of reconstruction. He has applied these concepts successfully to the treatment of congenital microtia in 2 boys, aged 5 and 6 years respectively. 1. The ear is visualized as a structure composed essentially of 4 separate planes —conchal floor, conchal wall, antihelix-scapha complex, and helix. The antihelix-scapha complex is the key component of the reconstruction. If the antihelix and scapha can be properly formed and positioned, then the remaining 3 components can be developed as adjuncts to the principal structural block, either at the time of construction of the block or later. 2. In every method the surgeon has introduced the framework through an incision at some point on the head peripheral to the proposed site of the helix. The author feels that, and explains why, it is advantageous to implant the auricular cartilage through a central incision in the conchal region. 3. A complete unit reproducing the entire ear cartilage is not only unnecessary but undesirable, because it is too bulky and makes adequate coverage by skin difficult. An antihelix-scapha-helix unit is much more practical. The largest rib of a 5-year-old child is not large enough to allow the carving of this unit. However, 2 rib cartilages placed side by side yield sufficient width and depth to permit the fashioning of a normal adult-sized antihelix-scapha unit. With this key component completed, it is then possible to carve a helix from another rib, warp it, and wire it perpendicular to the edge of the scapha. 4. In the normal ear from one-third to one-half of the conchal cavity lies below the adjacent skin level; hence, the conchal floor can be simply constructed by removing tissue in the form of a flap from the concha, rolling it forward under itself to produce a tragus, and implanting a free graft in the conchal defect. The creation of the wall of the conchal cavity, lying in a plane at right angles to that of the conchal floor and of the antihelix, while at the same time bringing the ear out at a proper angle to the side of the head, offers one of the major barriers to successful ear reconstruction. The author finally decided that the simultaneous production of the auriculocephalic angle and the construction of the conchal wall were impractical and that the logical solution was to bring the antihelix-scapha-helix unit outward into proper position like a valise handle, leaving the conchal wall deficient and constructing it at a later time from adjacent retroauricular tissue.

The author illustrates his technique with diagrams. While he has used this technique in only 2 patients, it is applicable to several types of microtia and adaptable, at least in some measure, to partial or total traumatic loss of the auricle. The reconstruction, as outlined, can be safely completed in one year rather than the 20 and 21 months employed in the 2 patients. With further experience it may prove feasible to reduce the plan to 4 steps: rotation of auricle and implantation of cartilage, formation of the "valise handle" in 2 stages, closure of the tunnel, and formation of tragus and conchal floor, all of which could be accomplished in a period of about 8 months. The method of constructing the cartilage assembly from costal cartilage has been used in 4 other unfinished cases of various types, with gratifying results in each instance.

Automobile Accidents: The Multiple Injury Patient. E. R. Shipley. Maryland M. J. 8:52-54 (Feb.) 1959 [Baltimore].

This report is concerned with 178 patients requiring hospitalization on account of automobile accidents at South Baltimore General Hospital. The physician in the accident room may be confronted not only with more than one victim of an accident but also with victims having multiple injuries. There are 3 emergencies in which life or death may depend on seconds: respiratory insufficiency, hemorrhage, and cessation of heart action. If respiratory insufficiency threatens because of obstruction of the air passage, a tracheotomy should not be delayed. A blind tracheotomy can be performed with a Sheldon tracheotome, or a large caliber needle may be inserted into the cricoid-thyroid membrane to admit air into the upper trachea, but the simple removal of blood and debris from the mouth and pharynx is usually sufficient. When respiratory embarrassment has its origin in the lungs, the administration of oxygen by positive pressure, endotracheal intubation, or manual breathing may be necessary. Respiratory insufficiency may be caused also by disruption of the pneumodynamics of the pleural space. An open sucking thoracotomy or a hemopneumothorax may prevent aeration of the lungs. Occlusion of the wound with a dressing is usually sufficient in a sucking wound of the chest. Immediate tapping and aspiration are essential in hemopneumothorax. When respiratory insufficiency is due to interruption of the blood supply through or to the lungs, the administration of atropine sulfate may overcome the massive vasospasm.

Cessation of heart action requires opening the chest and rhythmic manual compression of the heart. Injection of epinephrine directly into the heart is often tried but is frequently without avail. Overt hemorrhage is usually easily treated, but concealed hemorrhage may be difficult to detect. The area of injury should give a clue whether an intrathoracic or an intra-abdominal vessel is injured, and there should be no delay in operation.

After the 3 major emergencies have been properly managed, a complete examination should be carried out. The patient may be uncooperative, either because he is under the influence of alcohol or because of head injuries, and under these circumstances injuries may be overlooked. Even in the well-oriented, cooperative patient who has undergone an automobile accident, there are areas which do not hurt and which do not point to injury, but which may prove, within 24 to 48 hours, to be quite serious. A patient who complains of a broken shoulder, leg fractures, or massive lacerations, and does not complain of chest injuries, may on the following day be found to have pneumonitis as a result of broken ribs. The physician must carefully evaluate each patient for fractures of cervical or thoracic vertebrae. The whiplash type of injury to the neck is extremely common in automobile accidents, and it is quite disabling.

Head injuries ranked first among the severe injuries in the 178 patients; 60 had concussion or other severe injury of the brain. There were 141 fractures. Minor lacerations occurred in 67 patients, major lacerations in 16, chest injuries in 8, and abdominal injuries in 6. Only one patient had severe facial injuries, and one patient had a severe eye injury. Four patients suffered evulsions of the teeth. During the past year the number of pelvic fractures seems to have increased. Eighteen of the 141 fractures were pelvic fractures, and 55 of the fractures were in the lower extremities.

Resolving Scoliosis. J. C. Scott. J. Bone & Joint Surg. 41B:105-113 (Feb.) 1959 [London].

It has been generally accepted as a working hypothesis in scoliosis that, once a curve with structural changes is present in a growing child, it will gradually increase. The extent of the increase will depend on various factors, the most important single one being the length of the growth period still ahead of the patient. Some of the unknown factors can be exemplified by the markedly different types of curve in poliomyelitis—the paralytic type and the type which the author calls "idiopathic." No reliable evidence is yet available as to what is responsible for different curve patterns. In the study of the factors concerned, the variety of curve patterns, and their progress, the author had found that this gradual increase with varying speed did not always take place. At 6 months there was a high proportion of infants (80%) having a definite lateral curve of 10 degrees or more, and this decreased without treatment, so that the incidence had fallen to 7% by 18 months and none of these children had a measurable deformity by the age of 2 years. This state of affairs was considered to be a natural infantile alignment of the spine, and the disappearance of the curve was attributed to the assumption of the erect posture. A "resolving" type of infantile scoliosis was also described in which curves of 20 degrees with structural changes gradually disappeared over intervals up to 4 years.

In this paper the author reports on 4 children in whom infantile idiopathic structural scoliosis gradually decreased during the period of active growth. The curve patterns and progress suggested that "resolving" types of scoliosis may be much more frequent and variable than is at present appreciated. These cases are of particular interest in that they all fall into the infantile "idiopathic" group, and all might have been expected to proceed to severe deformity. They were recognized at a time when full spinal growth was ahead, and all had the type of structural changes so often seen in the early stages of the progressive curve. It is of interest that the curve pattern was the same in the 4 patients. The significance of this is slight in so small a number—many of the severe curves occupy this same area—but in the progressive type the apex tends to be higher and the curves shorter. None of these patients had any treatment which could have affected the outcome in any way.

NEUROLOGY & PSYCHIATRY

Preliminary Observations on Ego Development in Children with Congenital Defects of the Genitourinary System. A. D. Fineman. Am. J. Orthopsychiat. 29:110-120 (Jan.) 1959 [New York].

This study deals with the question of whether children with particular defects in the anatomy and function of the body parts normally used in the controlled rhythmic output of urine and feces would develop specific aberrations of personality structure. Ten males and 2 females with exstrophy of the bladder, their ages ranging from 3 to 26 years, were studied during a period of about one year. All patients in this series have been treated, or are being treated, by the same type of surgical corrective procedures, which are begun sometime between the ages of 4 and 6 years. This surgical intervention results in an intact body wall and fairly normal-appearing external genitalia. Excretion of both urine and feces occurs through the anus. The reproductive organs are functional; women with this condition may give birth to normal children without difficulty; the males have erections and emit seminal fluid.

The attitudes of the mothers of these patients with congenital defects varied from direct abandonment to extreme overprotection, involving refusal to bear more children and slavish devotion to the damaged child. Since most of them were born in small hospitals where physicians and nurses were unfamiliar with this particular anomaly, the mother did not receive the support of a correctly informed and understanding physician, which *seems to* be the most important factor in the very beginning of the mother's relationship to the child.

In those patients with exstrophy of the bladder in whom there existed a functional cloaca, the anal sphincter control appeared to take on functions more closely related to urination than to defecation. The problem of night wetting showed a close resemblance to enuresis, with the complication, however, that with these patients, soiling of the bedclothes was conceived of as a much dirtier process than merely wetting with urine. Body image concepts of being a receptacle filled with dirty fluid were common. A general frequency of bowel movements as well as a poor to nonexistent control of the excretion during the preoperative period has been reported by the mothers of 5 boys. Less difficulty than expected in the control of urinary and fecal excretion was observed in the children after the operation. The mother of a boy who was operated on at 3 years 10 months reported that he was untrained preoperatively but was completely dry, day and night, 7 months postoperatively. The child's capacity for control, in this case, seemed to be markedly influenced by the mother's expectations and her feelings about the curative effect of the operation.

Three adult male patients who were observed regarding the development of their personalities were characterized by a feeling of unreality; the level of social achievement seemed to have made little inroad on this feeling. They envisaged a life of solitude as their lot. Two women who were seen were similarly characterized by fearful avoidance of close relationships and repression of affect, but with them it seemed that the apparent affectless state was maintained more as a defense against feelings of being rejected, because of their own feelings of being damaged, ugly, or distorted. They did not present a picture of utter hopelessness, as did the men, where the sole alternatives were either to succumb or to deny. In the male children, denial and restitution fantasies were freely utilized. A 5½-year-old boy said, "I can pee through the front when I want to, sometimes, or when I get bigger." It is interesting that this child, who had been damaged since birth, nevertheless demonstrated the typical oedipal fantasy of the castrating father. A 12-year-old boy, who had been institutionalized since the age of 3, has responded well to therapy insofar as his bowel control, social adjustment, and school achievement are concerned, but he still demonstrates a desperate necessity to maintain his defensive barriers almost completely intact, as did the adult males. A 10-year-old boy with excellent bowel control protected himself with such rigidity that, even after a year of weekly interviews during which his warm attachment to the therapist was quite apparent, he could allow almost no communication about his bodily defects.

This rigid defensiveness of the older children and the adults, as compared with the younger children, was greater than the difference expected because of their ages. It appeared rather as though the reality of their bodily structure and function was just too painful to bear, and the denial mechanisms which they had developed had to be carefully guarded from the peril of reality testing. These patients lived in a state of chronic anxiety. However, they were definitely amenable to therapy. In all cases, the relationship developed with the therapist was a markedly dependent one, the progress of the patient for a considerable period of time being sustained by direct giving in terms of material gifts as well as ego building; the latter efforts were reinforced by parental support plus the aid of such accessory figures as school and medical personnel.

The Alimentary Route of Infection in Tick-Borne Encephalitis. E. N. Levkovich and V. V. Pogodina. Probl. Virol. (Translation from the Russian) 3:154-160 (no. 3) 1958 [New York].

Epidemiologic and serologic studies were made on 102 patients with tick-borne encephalitis transmitted by the alimentary route through milk during an epidemic in the Kemorovo province of the Soviet Union in 1955 and in the Sverdlovsk province in 1956. In only 7 of the 102 patients did the disease have a sporadic character; in the remaining 95 patients encephalitis occurred in family groups ranging from 2 to 8 patients per focus. The incidence of the disease was higher among the younger age groups, with 25% of all the cases occurring among children, aged less than 5 years. The transmission of the disease by the use of goat's milk by all the patients was undoubted, since only 3 of the 102 patients had been bitten by ticks, and the remaining 99 patients, most of whom lived in urban areas, had not been in contact with ticks. The incubation period varied from 1 to 14 days and most often from 3 to 9 days.

Neutralization tests with diminishing doses of the virus of tick-borne encephalitis (strain F), by the method of intracerebral titration in white mice, were carried out on serums obtained at different stages of the illness from patients and their goats. In 26 of 29 patients positive neutralization indexes (from 50 to 5,623) were obtained, increasing during convalescence in most of these patients. At the same time neutralizing antibodies were detected in the serums of the goats. In some of the patients infected by the alimentary route, the immune response developed slowly; serums obtained from these patients at the 4th, 5th, and even 8th week from the onset of the disease were negative, or doubtfully positive, with respect to their neutralization indexes, and diagnostically reliable antibody levels were found only on later examinations. Of 6 isolated strains of encephalitis virus, 5 were isolated from the blood of patients in the acute stage of the disease and 1 from the blood of a goat; in their biological and antigenic properties the strains were found to be identical with each other and with a reference strain of tick-borne encephalitis virus.

In order to verify the possibility of a latent infection of man through the raw milk of goats in a focus of tick-borne encephalitis in the Kemorovo province, observations were made on persons of the healthy population and their goats, which were kept in pastures heavily infested with ticks. By careful preliminary questioning, a group was selected from an urban population never in contact with ticks, never being affected by tick-borne encephalitis or vaccinated against it, and regularly using raw milk from their own goats. It was found that most of the goats examined (13 of 19) possessed considerable titers of neutralizing antibodies. Among the owners of goats using the milk in raw state, high antibody titers were also found, which in view of the conditions of selection of the group could be explained only by infection through the milk of the infected goats. For control purposes the neutralization indexes were determined in the serum obtained from the owners of goats who did not drink the milk or who used it only after boiling. The neutralization indexes of these persons were very low. The reported data revealed that in foci of tick-borne encephalitis latent immunization of the population is possible, not only as a result of direct contact with infected ticks but also through the use of raw milk from infected goats.

The Response to the Controlled Infection by Attenuated Poliomyelitis Virus in the Neonatal Period and Early Infancy. M. Martins Da Silva. Minnesota Med. 42:83-87 (Feb.) 1959 [St. Paul].

Of 138 pregnant women who were selected for vaccination with Salk vaccine, 69 received the vaccine intradermally (0.2 cc. twice, 3 to 4 weeks apart) and the other 69 women received the vaccine subcutaneously (1 cc. twice, 3 to 4 weeks apart). Blood samples were collected immediately before the first injection and about 4 weeks after the second injection. At delivery a third specimen of maternal blood and a sample of cord blood were obtained. Blood samples were collected from the infants at about 3-month intervals for one year or until no detectable antibody titers remained. Intradermal inoculation elicited as good an antibody response as the larger subcutaneous dose in those women whose antibody titers were measurable before and after vaccination. The 3 lots of commercially prepared Salk vaccine used varied in antigenic potency. Cord blood antibody titers were equal to or within one tube difference of maternal titer at delivery in 85% of the infants in whom such comparisons could be made. The "half-life" of types 1, 2, and 3 antibodies present in the neonatal period was 37 days regardless of the level of the cord blood titers. Detectable antibody titers were present at 9 months of age in most of the infants who had an antibody level of 1:1024 or greater at birth. These findings confirmed again that poliomyelitis antibodies are passively transferred in man from mother to infant.

To a group of 25 infants, aged less than 6 months, born of mothers vaccinated during pregnancy with Salk vaccine, type 1 attenuated poliomyelitis virus (SM strain) was given orally mixed in nursery formula or regular cow's milk. The presence of virus in the feces and the immune response in each infant were followed by serial cultures of feces at weekly intervals for 5 to 12 weeks and by serum antibody determinations at 1-month to 3-month intervals up to one year. No significant untoward reactions were observed in the infants fed the attenuated virus. The antibody titers obtained in these infants were above the expected levels of passive antibodies and represented "active" antibodies which presumably were the result of vaccination. Comparison of killed Salk vaccine with the living SM vaccine thus suggests that the placentally transferred passive immunity resulting from the vaccination of mothers with Salk vaccine can be converted to an actively acquired immunity by the oral administration of SM vaccine to the infant during the phase of declining protection of maternal antibodies.

Torulosis. M. G. F. Donnan. J. Fac. Radiologists **10**:17-20 (Jan.) 1959 [Bristol, England].

Recent case reports of torulosis (cryptococcosis) indicate an increasing recognition of the disease and of its world-wide distribution. The infecting organism, Cryptococcus neoformans, is a single cell which reproduces by budding. Surrounding the organism in the tissues is a clear zone of gelatinous material. The miliary nodule is the commonest pathological lesion. Where there is a paucity of organisms, the lesion may be a fibrotic granuloma. Where there is a massive proliferation of cryptococci, the lesion may be a gelatinous mass. The portal of entry may be the skin, intestinal tract, or respiratory tract, the last most commonly. Cure has been reported after removal of isolated lung lesions. Involvement of the brain and meninges is almost uniformly fatal. The 5 patients mentioned by the author were observed in the Royal Perth Hospital, Perth, Western Australia. Two cases had been described in 1955. Of the 3 newly presented here, 2 concerned aboriginal girls, aged 17 and 16 years, respectively; the third was that of a 41-year-old white man.

In the 17-year-old girl a rounded opacity lying at the left base was detected in a mass roentgenographic chest survey. She had had one episode of severe lower chest pain, but on admission she was asymptomatic. The ovoid opacity was not homogeneous in density, and tomography demonstrated multiple fusiform radiolucent areas. A degenerated hydatid cyst was suspected. At thoracotomy a hard tumor was felt lying under the pleura of the posterior surface of the lower lobe. Lobectomy was carried out. The cut surface of the specimen showed firm, creamy tissue. Microscopically the pale tissue was seen to be necrotic lung parenchyma. Among the necrotic tissue were numerous yeasts with the morphologic and histochemical characteristics of C. neoformans. The patient was well on discharge from hospital.

The 16-year-old girl was first admitted to a hospital for aborigines complaining of pain in the neck and exhibiting erratic acts—sudden loud cries, collapsing on the floor, and clumsiness on eating. Routine examination at first elicited nothing abnormal. Later, no tendon reflexes could be elicited, and there was papilledema and optic atrophy. The patient's mental state had deteriorated, and she was incontinent. She was admitted to the Royal Perth Hospital on Nov. 4, 1954. Physical examination and cytological and biochemical examination of the cerebrospinal fluid suggested a tuberculous meningitis, but the tubercle bacillus was neither identified nor cultured. Cerebral angiography was inconclusive. Ventricular drainage was instituted, but after 3 days the patient pulled the catheter out. Some days later cryptococci were found on direct smear of the cerebrospinal fluid obtained by lumbar puncture. The patient died on Jan. 1, 1955. Autopsy revealed extensive brain lesions and granulomas in the lung, which contained numerous cryptococci.

The 41-year-old man dated his symptoms of left-sided hemiparesis and hemianesthesia from an accidental blow to the face 8 months previously. Five years previously he had had a right lower lobectomy for bronchiectasis. The findings on roentgenoscopy of the skull suggested the possibility of a thalamic space-occupying lesion, but there was no papilledema and the cerebrospinal fluid was normal, and he was discharged. Several months later the patient was readmitted as unmanageable. There had been progression of his symptoms, and, in addition, he had headache and diplopia and was vomiting. Vomiting persisted; he became comatose and died several weeks later.

Autopsy revealed a large, gelatinous, light brownish mass occupying the right side of the thalamus and the hypothalamus. Inferiorly and medially, the mass extended into the midbrain. There was an old subarachnoid hemorrhage in the parietal region on the left and in this region was a brownish, wedge-shaped cystic infarct involving both cortex and white matter. The adjacent sulci contained fibrinous exudate which also appeared gelatinous. Histologically, the right side of the thalamus was a mass of cryptococci. The left-sided parietal cortex showed cortical invasion by cryptococci with some gliosis and spread of the organisms to the subarachnoid space, with a localized area of meningitis. Section of a small lung focus showed a mass of cryptococci with surrounding fibrosis. The final diagnosis was torulosis of the lung with spread to the parietal cortex and thalamus.

Some Peculiarities of the Seasonal Occurrence of Poliomyelitis in Finland. P. Nuorteva. Ann. med. exper. et biol. Fenniae 36:335-342 (no. 4) 1958 (In English) [Helsinki].

In the temperate climates poliomyelitis is prevalent in spring and summer. This epidemiologic behavior is poorly understood, as freezing does not inactivate the poliomyelitis virus. The assumption that flies or other arthropods act as tranmitters of poliomyelitis during the epidemics could offer an explanation for the epidemiologic behavior of this disease. In fact, viruses of poliomyelitis have been extracted from houseflies and from several species of blowflies collected during or before epidemics. In the present article, attention is drawn to some peculiar features in the seasonal occurrence of poliomyelitis in Finland, and an attempt is made to elucidate these peculiarities from an entomologist's point of view. The cases on which this report is based had been reported to the Medical Board of Finland during the years 1938-1957.

Notes on the flying times and geographical distribution of some flies are based on the records of the trapping dates and of the localities of these insects in the Entomologic Museum of Helsinki. The series examined for this paper consisted of more than 1,000 specimens of the genus Lucilia collected by different persons in 95 parishes situated in various parts of Finland. It was found that in 3 provinces along the southern coastal area of Finland poliomyelitis occurred somewhat later than in the other provinces. This fact can be correlated with the occurrence of the virus-spreading blowfly, L. sericata Meig., which occurs only in the southern coastal area and which shows a seasonal maximum of abundance later in the season than do other flies. The commoner occurrence of poliomyelitis in winter in the northern provinces than in the south is discussed in connection with a hypothetical transmission of the disease by overwintering flies and cockroaches.

Mental Disorders in Cerebral Cysticercosis. R. Jeri. Rev. psiq. peruana 1:211-227 (July-Dec.) 1958 (In Spanish) [Lima, Peru].

Thirty-two patients with cerebral cysticercosis were observed in the Sanatorio de Enfermedades Nerviosas y Mentales and in the department of mental diseases of the Instituto Nacional de Enfermedades Neoplásicas, both in Lima, Peru. Twenty-eight of the patients had mental disturbances. All the patients had a history of having suffered for a long time with headache, convulsions of all types of epilepsy, visual disorders, certain forms of paresis, and other neurological symptoms. In all of them the symptoms corresponded to a cerebral lesion (focal or diffuse) or a lesion in the infratentorial structures. One of the patients died in status epilepticus. A diagnosis of cerebral cysticercosis was made in 29 patients by the results of one, or more than one, of the techniques used in the diagnosis of neurosurgical diseases or else an explorative craniotomy; it was made during autopsy in 3 cases. Cysticercosis was cystic (single or multiple) in 10 cases, racemose in 8, and mixed cystic and racemose in 14. The foci of infestation by cysticerci were the cerebral hemispheres in 18 cases, the posterior cranial fossa in 31, and the spinal cord in 1. Some of the patients had simultaneously hemispheral, ventricular, and cisternal cysticercosis. The infestation was chronic in all cases. The mental disorders consisted of acute delirium, psychotic reactions of the chronic toxicoinfectious type, and severe changes of personality. Careful neuropsychiatric observation of the patients permitted reaching a diagnosis of cerebral cysticercosis after elimination of the diagnoses of schizophrenia or manic-depressive reaction previously made in the patients.

The author concludes that examination of the central nervous system by means of rachicentesis, radiology of the cranium, ventriculography, and explorative craniotomy is indispensable in all patients with associated focal or diffuse neurological symptoms, mental disturbances, and convulsions, in search of clues for cerebral cysticercosis as the cause of the mental disorder. There is no relation between the acuteness and type of psychosis and the type and cerebral location of cysticercosis and extension of the infected foci, except in cases of chronic racemose cysticercosis. In the latter form the severity of dementia parallels the extension of atrophy, which results from both the obstructive hydrocephalus and the disorders of local circulation which follow cysticercotic periarteritis and endoarteritis.

GYNECOLOGY & OBSTETRICS

A Little-Known Form of Mammary Dystrophy: Dilated and Secreting Lactiferous Ducts. G. Seillé and J. de Brux. Presse méd. 66:2051-2053 (Dec. 25) 1958 (In French) [Paris].

The syndrome of dilated and secreting lactiferous ducts is not well known. It was observed by the authors in 10 women during a period of 6 months; one patient was 40 years of age, and the others were in the period immediately preceding or following the menopause. The clinical symptoms of this syndrome vary. The secretion may appear as a milky discharge from the breast in a filiform spurt on moderate compression of an area on or around the areola mammae. A small, painful tumor may be present in, or absent from, the area under the areola. Alternatively, the milky secretion of the mammary glands in women at the menopause may accumulate in the ampullae of the lactiferous ducts in the region of the areola without being excreted from, or reabsorbed by, the body. This benign lesion consists of a dilatation, from 3 to 7 mm. in diameter, of 3 to 20 bluish lactiferous ducts under the areola, which ducts undergo a scleroinflammatory process. The syndrome is macroscopically distinguishable from malignancy, *since incising the affected lactiferous ducts produces* a milky discharge instead of dark-red blood. If the tumor is related to a subsequent suppurative process, with ulceration of the skin and fistulization, an erroneous diagnosis of tuberculosis may ensue. Microscopic examination of the milky discharge reveals the presence of lipids, desquamated cells of small vessels, and absence of both blood corpuscles and epitheliomatous cells.

The correct diagnosis of this syndrome prevents performance of unnecessary mastectomy. Treatment is surgical, being similar to the operation for dendritic adenoma. If the lesion is associated with inflammation, a combined cortisone and local or general antibiotic therapy is recommended preoperatively. The authors believe that the etiology of this syndrome is unrelated to a lactational disorder, but may be attributed to either a dystrophic lesion or an unexpected secretion of a quiescent gland.

A Study on the Behavior of C-Reactive Protein During the Puerperium and in Normal Conditions. F. Calapà. Minerva ginec. 10:885-888 (Nov. 30) 1958 (In Italian) [Turin, Italy].

The presence of C-reactive protein was studied in 60 normal pregnant women—10 in the first trimester of pregnancy, 20 in the second trimester, and 30 in the third trimester; in 90 women in labor after a normal pregnancy—50 women were in the dilating phase and 40 in the expulsive phase; in 80 normal puerperas—80 were followed from the 1st to the 7th day, and 20 from the 8th to the 14th day after labor; and in 5 women in whom the behavior of C-reactive protein was followed from the third trimester of pregnancy to the 7th day of the puerperium. Two methods based upon an *immunological response* were used: (*a*) the agglutination reaction with specific rabbit antiserum (McLeod and Avery method) and (*b*) the complement-fixation reaction with rabbit antiserum (Mushel and Weatherwax method). No difference was found in the results obtained by the 2 methods. The search for C-reactive protein gave positive results in 30% of all the tests made. Positivity was not so frequent during the first months of pregnancy but tended to become more frequent with the advancement of pregnancy; positive results were obtained in 10% of the patients in the first trimester of pregnancy, in 25% of those in the second trimester, and in 40% of those in the third trimester. Positive results were frequent in patients in labor—in 36% of the patients in the dilating phase and in 100% of those in the expulsive phase. Marked positive results were obtained in the tests given to the puerperas—in 76% of the patients followed from the 1st to the 7th day of the puerperium and in 60% of those followed from the 8th to the 14th day. The positivity of the *C-reactive protein tests given to the 5 patients* followed from the third trimester of pregnancy to the 7th day of the puerperium became marked during labor and increased more so during the first few days of the puerperium. The author concludes that in normal pregnancy C-reactive protein appears in the serum around the 7th month of pregnancy and that it increases with the evolution of pregnancy, during labor, and during the puerperium.

Effect of Serotonin upon Labor in Women. A. Valsecchi. Minerva ginec. 10:898-901 (Nov. 30) 1958 (In Italian) [Turin, Italy].

The effect of serotonin was studied in a group of 22 women, 16 primiparas and 6 pluriparas, in whom labor was induced because of uterine inertia, or premature rupture of the membrane with infection of the amniotic fluid, or prolonged pregnancy. Each patient received a 10-mg. intramuscular injection of a double salt of serotonin (5-hydroxytryptamine creatinine sulfate); a second injection of 10 mg. was given *intramuscularly* after 30 minutes, and a third injection of 5 mg. after 2 hours. In some women serotonin was given because other drugs administered previously had had no effect. During the administration of serotonin it was observed that tachycardia, present at the beginning of the injection, decreased progressively and that after a maximum of 20 minutes it had disappeared; the blood pressure went up 10 to 25 mm. Hg in 12 patients but returned to normal values after a maximum of 15 minutes; and tachypnea lasting 30 to 60 seconds was observed in 8 patients, but disappeared as soon as the administration of the drug was suspended. Bradycardia of the fetus occurred in 15 patients, but this phenomenon did not indicate that the drug caused suffering to the fetus, since all the living infants were born normal; treatment of one patient was started when the fetus was already dead, and in 2 other patients the suffering of the fetus was caused by dystocia of the umbilical cord. Of the 22 patients in whom it was necessary to induce labor, 13 presented an excellent and satisfactory course with expulsion of the fetus; failures were observed in the remaining 9 patients. The author believes that a particular endocrine equilibrium is necessary in order that serotonin may be able to manifest its oxytocic effect. The drug caused brief, but significant, changes in the cardiocirculatory and respiratory systems of the mother and had some effect as well on the heart beat of the fetus. Passage of serotonin through the placenta is believed to be possible.

THERAPEUTICS

Triamcinolone in Rheumatoid Arthritis and Psoriatic Arthritis. S. J. Bosch, O. García Morteo, A. Porrini and others. Medicina 18:103-108 (June) 1958 (In Spanish) [Buenos Aires].

Triamcinolone (9-alpha-fluoro-16-alpha-hydroxy-prednisolone) was given to a group of 19 patients, made up of 15 patients with rheumatoid arthritis and 4 with psoriatic arthritis. Most of the patients were women, between the ages of 19 and 69 years. When triamcinolone therapy was started, 11 patients had failed to respond to prednisone administered for a long period, 2 were receiving corticotropin (ACTH), and 6 had not had any previous steroid treatment. Triamcinolone was given in daily amounts of 12 mg. divided into 4 doses. The drug was given uninterruptedly for a period which varied between 1 month and 4 months. In the majority of the patients the daily maintenance dosage also proved to be 12 mg. The functional capacity improved greatly in all the patients who had a capacity of the first and the second class; it improved moderately in those with a capacity of the third class and in one of the 2 patients with a functional capacity of the fourth class. In the whole group of 19 patients there was complete remission of the arthritis in 4 patients, great improvement in 8, moderate improvement in 5, and failure of the treatment in 2. In cases of psoriasis there was complete remission of the skin disease in 1 patient and great improvement in 3. In all cases peeling of the psoriatic lesions and their size diminished, and pruritus entirely disappeared. All the patients with psoriasis stated that the relief afforded by triamcinolone had never been obtained with any other treatment. There was a loss of weight (from 1 to 6 kg. [3 to 13 lb.]) during the treatment in 10 patients. Six patients complained of excessive gastric acidity, which made it necessary to stop the treatment in one patient. Two patients complained about nausea and dizziness, 2 showed moderate hypertension, and 2 experienced debility of the legs. Nine patients had moon face, but they had it before the administration of triamcinolone as a result of previous treatment. None of the patients had edema. The authors conclude that the results of the treatment are promising. However, the observations are still recent. A greater number of patients and observations on them for longer periods will be necessary to reach conclusions.

Clinical Experiences with the Antibiotic Sigmamycin, with Particular Consideration of Its Effect on the Intestinal Flora. R. Blass. Schweiz. med. Wchnschr. 89:158-161 (Feb. 7) 1959 (In German) [Basel, Switzerland].

The author reports on 117 patients with various infections, such as pneumonia, abscess, furunculosis, phlegmon, paronychia, osteomyelitis, lymphadenitis, pleural empyema, peritonitis, urogenital infections, and wound infections, who were treated with Sigmamycin, an antibiotic compound of tetracycline and oleandomycin, at the surgical clinic of the University in Zurich, Switzerland. As a rule, 1.5 Gm. of the drug in 3 subdivided doses at 8-hour intervals was given daily for 5 days. Bacteriological examination of the feces was carried out before the institution of therapy and on the 5th day of therapy. Of the 117 patients, 93 had been treated unsuccessfully for 3 to 21 days with streptomycin and penicillin before the institution of Sigmamycin therapy; the remaining 24 were treated primarily with Sigmamycin. In 48 of the 117 patients the causative agent was Staphylococcus pyogenes var. aureus, and in the other patients various gram-positive and gram-negative causative agents were found. The results obtained showed the high effectiveness of Sigmamycin, particularly in the patients with suppurative infections, most of which were caused by Staph. pyogenes var. aureus. By breaking through the resistance of the latter causative agent, especially in cases of typical endemic hospital infections, Sigmamycin proved to be a valuable addition to the medicinal armamentarium.

Disturbances of the intestinal flora which had been observed in patients treated with broad-spectrum antibiotics were observed again in the patients treated with Sigmamycin. Considerable reduction in the titers of Escherichia coli and Aerobacter organisms to numbers ranging from 1,000 to 10,000 and less was observed in 17 patients

(14%). In 46 patients variations in titer values were not observed, and in the remaining 54 patients the titer values were reduced, but not below one million bacteria per gram of feces. The frequency of intestinal evacuations was running parallel with the reduction in Escherichia and Aerobacter titers. In general, the consistence and amount of the feces decreased in the course of the administration of Sigmamycin. Diarrhea occurred only in 6 cachectic patients of advanced age. In only 2 of the 6 patients were the titer values considerably decreased and resistant bacteria present in large amounts. The results of the bacterial examination of the feces remained normal in the 4 other patients.

These observations make the frequently reported relationship of enteritic phenomena with the occasionally severe disturbances in the intestinal flora depending on the administration of antibiotics questionable. Despite the few untoward reactions to Sigmamycin in this series, its use may occasionally interfere seriously with the balance of the micro-organisms in the intestine; therefore, penicillin and streptomycin, which are the best tolerated antibiotics, should always be given first choice, and Sigmamycin second choice.

Thioctic Acid and the Modifications of Lipid Metabolism in Cardioangiopathic Atherosclerotic Patients. R. Cattaneo, E. Levi and C. Prinotti. Acta gerontol. 8:123-140 (July-Sept.) 1958 (In Italian) [Milan, Italy].

The therapeutic effect of thioctic acid was studied in 15 patients with hypercholesteremia. The patients ranged in age from 48 to 70 years (average, 58), and all of them had vascular or cardiac disease with a definite tendency toward atherosclerosis or arteriosclerosis. The lowest value of total cholesterol in the serum was 206 mg. per 100 cc., and the highest was 322 mg. per 100 cc. The patients received one intramuscular injection of 50 mg. of thioctic acid each day for 7 consecutive days. The values of cholesterol were determined at the beginning and again at the end of treatment. Treatment with thioctic acid caused a marked drop in the cholesterol level. Total cholesterol dropped from an average of 245 mg. per 100 cc. to an average of 213 mg. per 100 cc. (a 13% drop); esters of cholesterol dropped from an average of 223 mg. per 100 cc. to an average of 184 mg. per 100 cc. (a 17% drop); combined cholesterol dropped from an average of 132 mg. per 100 cc. to an average of 109 mg. per 100 cc. (a 17% drop); and free cholesterol dropped from an average of 112 mg. per 100 cc. to an average of 104 mg. per 100 cc. (a 7% drop). Alpha-lipoproteins increased from an average of 19.4 mg. per 100 cc. to an average of 24.4 mg. per 100 cc. (a 26% increase), and beta-lipoproteins dropped from an average of 80.6 mg. per 100 cc. to an average of 75.6 mg. per 100 cc. (a 6% drop). The authors think that the effect of thioctic acid is such that, if it is permanent (their observations were limited to a very short period of time), the acid can be used effectively in the treatment of patients with hypercholesteremia.

Thrombocytopenia During Chlorothiazide Treatment. P. Nordquist, G. Cramer and P. Björntorp. Lancet 1:271-272 (Feb. 7) 1959 [London].

The authors describe observations on 6 patients in whom thrombocytopenia developed during treatment with the orally administered diuretic compound, chlorothiazide. Three of them also had a purpuric rash. To confirm that chlorothiazide was the cause of the thrombocytopenia, test doses were given and in vitro tests were made in 2 of the patients, and patch tests were performed in 3. The in vitro tests were: (1) inhibition of clot retraction, (2) immune-precipitate formation, and (3) platelet agglutination and lysis. In addition, platelet agglutination was studied on stained blood films. In 2 of the patients there was a direct connection between chlorothiazide and the thrombocytopenia, and a third showed positive in vitro tests for chlorothiazide.

Chlorothiazide was used at the clinic with which the authors are connected in about 400 patients last year, which indicates that a decrease in circulating platelets may appear in more than 1% of the patients. The thrombocytopenia was the only toxic manifestation of chlorothiazide in the bone marrow. The reaction was usually brief, and the platelet count returned to normal as soon as chlorothiazide was withdrawn. These observations indicate the desirability of doing a blood cell count when chlorothiazide is given to older and debilitated patients, or when it is combined with other drugs that may have a depressing effect on the hematopoietic system.

Acute Hepatic Necrosis Following Iproniazid Therapy: Value of Glutamic-Oxaloacetic Transaminase Estimation in Early Detection. C. M. B. Pare and M. Sandler. Lancet 1:282-284 (Feb. 7) 1959 [London].

The authors present 2 patients in whom acute hepatic necrosis developed after iproniazid therapy. One patient, who recovered, was being treated for intractable angina of effort; the other, who died, was taking part in a trial of this drug in the treatment of depression. When during this trial it became known that liver damage occasionally develops after treatment with iproniazid, the authors carried out liver function tests in order to detect early changes which might indicate this complication. The determination of the serum glutamic oxalacetic transaminase (SGO-T) level has recently come into extensive use as an index of hepatocellular damage. The authors estimated the SGO-T level in 29 patients undergoing treatment with iproniazid, and they found raised levels in 9. While the significance of this finding is still uncertain, in the interest of the safety of the patients a raised SGO-T level should be regarded as presumptive evidence of early hepatic damage, and discontinuance of treatment with iproniazid would seem advisable.

PATHOLOGY

On the Role of the Thyroid in Native Resistance to Tuberculosis: I. The Effect of Hyperthyroidism.

M. B. Lurie, P. Zappasodi, R. S. Levy and R. G. Blaker. Am. Rev. Tuberc. 79:152-179 (Feb.) 1959 [New York].

Since thyroid hormones increase the metabolism of cells and accelerate growth and differentiation, experiments were performed on about 350 rabbits, belonging to 8 different races of different genetic resistance to tuberculosis and of varying degrees of inbreeding, in an attempt to ascertain whether the native resistance to tuberculosis might be increased in certain races by increasing the amount of thyroid hormones available to the tissues. The effect of hyperthyroidism was tested on the same genetic strain with litter mates in the control-test and experimental groups. Hyperthyroidism was induced by the administration of L-triiodothyronine or L-thyroxin intramuscularly for 2 to 4 weeks before the exposure to a single quantitative inhalation of virulent human tubercle bacilli, H37Rv. Injections of the hormones then were made daily or 3 times weekly during the course of the resultant tuberculous infection.

The results showed that hyperthyroidism induced by the administration of the 2 hormones utilized in these experiments suppressed to a greater or less degree the inception and progress of the pulmonary tuberculosis produced by the quantitative inhalation of human tubercle bacilli in 4 races of rabbits with low or intermediate genetic resistance to the disease. L-triiodothyronine, a substance which is 2 to 5 times more active than L-thyroxin, also exerted a definite suppressive influence on the development of an already existing tuberculosis when the hormone was administered 3 weeks after the infection. The native resistance of the highly inbred and most susceptible rabbit race could not be materially increased by this treatment. By cultural methods it was found that the administration of both the hormones utilized in the experiments markedly restrained the accumulation of bacilli in the lungs and increased, to a varying degree, their spread to the draining lymph nodes. Microscopic studies substantiated the gross and cultural observations. Whenever these hormones exerted a conspicuous inhibitory effect on the inception and progress of tuberculosis, there was a concomitant sharp reduction in tuberculin sensitivity.

The difference in host-parasite relationships between treated and untreated rabbits of the same genetic resistance was of the same bacteriological and pathological nature as that between untreated natively resistant and susceptible rabbits. Genetic resistance is characterized by high innate ability of the tissues to inhibit the accumulation of tubercle bacilli and by a marked spread of the bacilli from the portal of entry to the draining lymph nodes. The administration of thyroid hormones to certain races is likewise characterized by an increased inhibitory capacity of their tissues against the accumulation of tubercle bacilli, by an enhancement of the spread of the bacilli from the lung to the draining nodes, and by an increased resistance to the disease.

On the Role of the Thyroid in Native Resistance to Tuberculosis: II. The Effect of Hypothyroidism: The Mode of Action of Thyroid Hormones.

M. B. Lurie, P. Zappasodi, R. G. Blaker and R. S. Levy. Am. Rev. Tuberc. 79:180-203 (Feb.) 1959 [New York].

Since the data reported in the preceding paper showed that hyperthyroidism increases resistance to tuberculosis, it should follow that hypothyroidism would reduce it. In an attempt to confirm this assumption, hypothyroidism was produced by thyroidectomy, or by the subcutaneous administration of 100 mg. of propylthiouracil suspended in sodium chloride solution 5 times a week, in rabbits of 3 of the 8 races used in the previous experiments (1 of very high resistance, 1 of intermediate resistance, and 1 of low resistance), which were then exposed to the quantitative inhalation of virulent human tubercle bacilli as in the preceding study.

The results showed that hypothyroidism induced by thyroidectomy or the administration of propylthiouracil reduced the native resistance of the inbred rabbits to the inception and progress of tuberculosis. This was largely effected by an enhancement of the accumulation of the bacilli in the tissues and the consequent extension of caseation. Thyroidectomy tended to induce a marked atrophy of the spleen, in contrast to the hypertrophy of the spleen induced by thyroid hormone treatment; propylthiouracil did not produce any change in the spleen. Despite the marked accumulation of bacilli in the lesions of hypothyroid rabbits, their tuberculin sensitivity was markedly reduced, particularly in rabbits which had undergone thyroidectomy. Similarly the perifocal inflammation about the extensive caseous foci in the latter was reduced. This is ascribed to the reduced inflammatory irritability of the tissues in the hypothyroid state. The host-parasite relationship in the hypothyroid rabbits is, in many respects, similar to that of natively susceptible rabbits or rabbits under the influence of cortisone; this relationship in hyperthyroid rabbits is similar to natively resistant animals. These parallels were shown by the growth and destruction of bacilli, by the extent of caseation, and (to some extent) by the spread of bacilli from the site of invasion.

Concerning the mode of action of thyroid states on enhancing or suppressing the growth of bacilli, mere increase in oxygen consumption is not a factor in this process, for dinitrophenol, a calorigenic agent, reduced resistance and increased the number of bacilli in the lesions; and an elevation of the metabolic rate of certain races by triiodothyronine failed to increase resistance. In certain rabbits, hyperthyroidism tended to accelerate antibody formation to a nonspecific antigen, bovine serum albumin. Thyroidectomy definitely and significantly retarded and depressed antibody formation to this antigen. Whether this is due to a reduction of individual cellular activity or to other factors has not been determined. There was no difference in the basal metabolic rate of natively resistant and susceptible rabbits; however, tuberculosis caused hypertrophy of the thyroid gland in certain untreated rabbits. The differing host-parasite relationships in different thyroid states are consistent with the concept that thyroid function is one of the constitutional factors controlling native resistance to tuberculosis in rabbits.

On the Presence in the Human Saliva of a Hemoagglutination-Inhibiting Factor Affecting the Parotitic (Mumps) Virus. C. A. Romanzi and P. Filippi. Gior. batt. e immunol. 51:229-237 (May-Oct.) 1958 (In Italian) [Turin, Italy].

The authors studied the influence of human saliva on the hemoagglutination activity and the infective power of the mumps virus. The saliva was collected from normal adults in a quantity of 20 to 30 cc. on an empty stomach. The mumps virus used was of the Enders strain, and at the moment of the tests it had a hemoagglutination value of 1/640 and an infective value of $10^{-4.6}$. Results of tests relative to the effect of undiluted saliva on scalar dilutions of the virus showed that the saliva had a marked hemoagglutination-inhibiting effect; the intensity of these results varied according to the subject who had given the saliva and the day when the saliva was given. Storing the saliva at 4 C decreased slightly its hemoagglutination-inhibiting effect. Other tests showed that saliva had no effect on the infective power of the mumps virus inoculated in embryonated chicken eggs. Tests on the direct effect of saliva on erythrocytes showed that in most cases the treatment of red blood corpuscles with saliva did not interfere with the agglutination of the same corpuscles by the mumps virus, showing that the hemoagglutination-inhibiting effect takes place directly on the virus rather than on the red blood corpuscles. Spontaneous agglutination of the red blood corpuscles after contact with the saliva occurred in a few cases. Heating of the saliva at 56 C for 30 minutes did not cause any changes in the results. Tests made to compare the hemoagglutination-inhibiting effect of saliva and the hemoagglutination-inhibiting effect possessed by the serum of the same subject showed that the 2 effects are completely separated and that the effect of saliva is not due to the possible presence of serum antibodies within the same saliva. The authors believe that saliva contains an inhibiting "element" which acts on the mumps virus and checks its hemoagglutination activity.

Fatigue and Tumors: On the Influence of Fatigue Induced by Swimming on the Development of Lipschütz Ascites Tumor in Mice. L. A. Ardoino and S. Matracia. Cancro 11:392-405 (no. 5) 1958 (In Italian) [Turin, Italy].

A number of male and female mice were inoculated intraperitoneally with 25 cc. of Lipschütz polyploid ascites tumor. Some of the animals were kept as a contratest group, and the rest were subjected to fatigue by making them swim in water at 28 to 30 C for 45 minutes every day for 12 days. The animals were weighed before the inoculation of the tumor cells, on the 6th day after the inoculation, and on the 12th day; on the latter day they were killed by decapitation. A slight increase in body weight and a marked reduction in the total volume of ascites tumor were found in the animals subjected to fatigue as compared with the contratest animals. The average volume of ascites tumor of 18 animals subjected to fatigue was 1.61 cc., and in 18 contratest animals it was 6.55 cc. The total number of tumor cells contained in the ascitic fluid from the test mice subjected to fatigue was much lower than that from the contratest mice. The mitotic rate was low in the test mice, and when the ascitic fluid obtained from them was rendered cell-free by centrifugation, it was generally less turbid than the fluid from the contratest mice.

There was no difference in the ultraviolet absorption spectrums of the cell-free fluids from the two groups of mice. In both groups the ascitic fluid showed substances which had the spectrum of nucleoproteins, being characterized by a curve with a high of 2750 A and a low of 2500 A. Small masses of solid tumor were found frequently in the abdominal cavity of animals subjected to fatigue; these masses were absent in the contratest animals. The small masses of tumor had developed mainly on the serous coat, in the tunica muscularis of the intestinal loops, and in the mesenteric tissue; growth on the parietal layer of the peritoneum was rare. The authors believe that the differences in results obtained in the group of mice subjected to fatigue were caused by the stressing effect of the fatigue, and especially by the changes in the phlogistic reactivity of the vascular and mesenchymal tissues which play an important role in the growth of tumor.

Carcinoma of the Renal Cortex: Pathology and Prognosis. J. H. Childers. Texas J. Med. 55:96-98 (Feb.) 1959 [Austin].

Gross pathological and microscopic studies were performed by the author on specimens obtained during surgery or at autopsy from 47 patients with carcinoma of the renal cortex, who were admitted to the University of Texas Medical Branch Hospitals in Galveston between January, 1945, and December, 1954. The average age of these patients was 56.8 years. Thirty-one patients were men, and 16 were women. Only 39 of the 47 patients were suitable for detailed study, since the condition of 8 was diagnosed by histological study of tissue removed for biopsy and since they subsequently did not have a nephrectomy or autopsy. In each of these 8 patients roentgenologic and clinical studies confirmed the biopsy diagnosis of carcinoma of the kidney. In reviewing the 39 surgical and autopsy specimens, gross pathological changes were recorded. The diameter of the mass, as recorded in 38 patients, was less than 5 cm. in 4 patients, 5 to 10 cm. in 22, and more than 10 cm. in 12. The major part of the mass was located in the upper pole in 16 patients, in the midportion in 1, and in the lower pole in 7; in 11 patients it replaced most of the kidney. Multiple sections were studied from each neoplasm to determine the predominant cell type, grade of the neoplasm, extension, and vascular involvement. Twenty cases were classed as clear-cell type, 11 as granular-cell type, and 8 as mixed (granular-cell and clear-cell) type. The cases were classified according to the index of Hand and Broders; 7 cases were classed as grade 1 (least malignant), 17 as grade 2, 14 as grade 3, and 1 as grade 4. Sections taken at the hilar region of the kidney confirmed the gross observations of vein invasion in 10 instances and revealed microscopically areas of vascular invasion in 10 additional cases. Microscopic evidence of vein involvement was present in 20 patients.

Follow-up information was obtained early in 1958 regarding the present status of 8 patients in this series who are still living from 41 to 98 months after the operation. Thirty-seven patients of the total series died, and 2 patients were lost to follow-up. A favorable prognosis, as seen in these 8 patients, could not be correlated with age, sex, size of the mass, ulceration of the pelvis, extension through the capsule, histological grade, association with renal calculi, hemorrhage, or necrosis. Two of the 8 patients survived 98 and 44 months in spite of metastatic pulmonary disease. The presence of gross areas of calcification in the cut sections of the neoplasm was mentioned in 6 cases; 3 of these patients were alive and had an average survival of 63 months at the time of follow-up. Three patients with findings of vascular invasion had an average survival rate of 58 months after nephrectomy, which shows that demonstration of vascular invasion should not be construed as a hopeless sign. Four of the 8 living patients had neoplasms composed of clear cells, and 4 had neoplasms of the clear-cell and granular-cell variety. For all 39 patients, the survival rate was 40 months in patients with the finding of mixed (clear-cell and granular-cell) type of carcinoma; in those with clear-cell type of carcinoma it was 20 months; and in those with granular-cell type of carcinoma it was 8.4 months.

Carcinoid in the Duodenum. P. E. Rasmussen. Ugesk. læger 121:13-15 (Jan. 1) 1959 (In Danish) [Copenhagen].

Carcinoids are tumors developed from the argentaffin cells, cells of Kultschitzky, at the bottom of the Lieberkühn crypts in the intestine. These tumors are potentially malignant and, depending on the location, tend to metastasize to the regionary lymph nodes and the liver. The appendicular carcinoids are almost always benign; from 20 to 75% of the extra-appendicular tumors are considered to be malignant. The appendicular carcinoids are found twice as often in women as in men, with average age of 25 years, while the others are equally apportioned between the sexes, with average age of 55. The so-called carcinoid syndrome, attributed to an increased blood content of serotonin, secreted by the Kultschitzky cells, comprises carcinoid with extensive metastases, pulmonary stenosis or tricuspid lesion, and intermittent flush in the face and possibly on the extremities. While the diagnosis of carcinoid could earlier be made only at operation and histological examination, preoperative diagnosis is now possible by the establishment of the carcinoid syndrome and/or establishment of an increased serotonin content of the blood and urine. Because of the potential malignity, the disease should be treated as cancer, although patients with metastases to the liver have lived up to 20 years after diagnosis. Complete removal of the tumor and all metastases is thought to give a good chance of cure or at least a long period free from symptoms.

Postoperative diagnosis of carcinoid was made in a woman, aged 64 years, who had had repeated hematemesis for 9 years. No metastases were demonstrable at operation. There was a heart disorder, and auscultation pointed to affection of the tricuspid valves. The patient's face was remarkably flushed. Examination of the urine for serotonin about 2 weeks after operative removal of the tumor gave negative results. A month and a half after the operation marked paling of the ruddy complexion had occurred. The hemorrhages are ascribed to erosions of the mucous membrane over the tumor or stasis bleeding from pressure of the tumor on the mucous membrane.

Some Effects of Stenosis of the Terminal Common Bile Duct on the Biliary Tract and Liver: An Experimental Study. J. V. Pikula and J. E. Dunphy. New England J. Med. 260:315-318 (Feb. 12) 1959 [Boston].

Obstruction to the flow of bile has been considered an important factor in the formation of gallstones. The authors cite investigators who suggested that stenosis of the terminal biliary papilla or sphincter may be an important cause of gallstones. To investigate this possibility further, incomplete stricture of the lower common bile duct was produced in 13 dogs. A band of Cellophane was sutured around the lower common bile duct. In 7 experiments the band was lightly sprinkled with sodium dicetyl phosphate. The serum alkaline phosphatase, the electrophoretic pattern of serum alkaline phosphatase and serum proteins, the serum bilirubin, the color of the stools, and biopsies of the liver were studied at intervals until the experiment was completed by the death or killing of the animal. In 5 animals the pressure within the biliary tract was determined. At postmortem examination the degree of stricture was ascertained, and the biliary passages and liver were examined grossly and microscopically. It was found that incomplete stricture of the lower common bile duct in dogs was associated with a rapid elevation of serum alkaline phosphatase, variable elevation of serum bilirubin, and progressive biliary cirrhosis. Gallstones occurred in 5 of 9 experiments in which an incomplete stricture without acholic stools was produced. It was not clear why the serum alkaline phosphatase should be lower in the animals with jaundice and in which gallstones formed.

If one assumes that the source of the serum alkaline phosphatase is the epithelium of the biliary passages, it may be that in the more extreme degrees of obstruction in which jaundice develops and gallstones form, there is interference with the function of the biliary epithelium and hence a lower alkaline phosphatase. It is also evident that under the conditions of these experiments the development of gallstones is but one facet of a derangement of biliary and hepatic function characterized by stasis, high alkaline phosphatase, varying degrees of jaundice, and extensive gross and microscopic damage to the liver. The experimental syndrome is much closer to the clinical picture of cholangiolitic hepatitis or primary biliary cirrhosis than it is to uncomplicated cholelithiasis in man. Since it is rare in man to have such marked derangement of hepatic and biliary tract function in association with gallstones, the present study does not provide confirmatory evidence that stenosis of the biliary tract is a common primary cause of gallstones in man. The degree of stenosis in these experiments may be a crucial determining factor. The present study does not exclude the possibility that very slight stenosis or malfunction of the lower common bile duct leads to gallstones without the development of concomitant extensive disease in the liver.

ANESTHESIA

Anileridine as an Anesthetic Agent. J. T. Stage. Internat. J. Anesth. 6:25-28 (Jan.) 1959 [Baltimore].

Anileridine (Leritine) is a new narcotic agent with an analgesic potency approaching that of morphine and several times greater than that of meperidine. The analgesic effect begins within 15 to 30 minutes after administration and lasts from 5 to 6 hours. In dogs, subcutaneous administration of 8 mg. of anileridine per kilogram of body weight produces strong analgesia lasting for over 6 hours. Unlike morphine, anileridine has shown no emetic action in dogs. The compound is also effective orally. Nalorphine reverses the action of anileridine, antagonizing both the analgesic effect and the mild respiratory depression produced by the drug.

The author used anileridine in a series of 100 patients undergoing various surgical procedures. He administered the compound in place of meperidine as a primary anesthetic agent, in conjunction with nitrous oxide, thiopental sodium, and tubocurarine. Initial trials with intermittent doses were later abandoned in favor of the continuous drip method. Anileridine appeared to be more potent than meperidine, and with the drip method no significant apnea or hypotension occurred. Patients responded to command before leaving the operating table, and manifested little excitement on awakening. Analgesia appeared to persist up to 3 hours postoperatively. The new narcotic appeared to be a safe and satisfactory compound for use as a primary anesthetic agent. The combination of anileridine with nitrous oxide, thiopental sodium, and tubocurarine provided an adequate, controllable, and nonexplosive mixture.

The Use of Heparin to Minimize Thrombocytopenia and Bleeding Tendency During Hypothermia. R. H. Wensel and W. G. Bigelow. Surgery 45:223-228 (Feb.) 1959 [St. Louis].

Preliminary experiments on dogs showed that in the animals subjected to an anesthetic alone there was no alteration in platelet levels, while in hypothermic anesthetized dogs the fall of platelets averaged 63% of the normal count. The greatest fall occurred at the lowest temperatures reached. In dogs which were cooled, anesthetized, and given heparin in doses ranging from 0.5 to 1 mg. per kilogram of body weight, the fall of platelets averaged 41% of the normal count. No hemorrhage was noted in either the heparinized or the nonheparinized animals.

The influence of heparin on hypothermic thrombocytopenia was tested in 12 consecutive adult patients undergoing hypothermia for open heart surgery, chiefly the repair of atrial septal defects. The first 6 of the 12 patients received no heparin before the induction of hypothermia. The second 6 patients received 15 to 20 mg. of heparin intravenously before the induction of hypothermia. Platelet counts were taken before the induction at 35 C (95 F), and at 5-degree intervals thereafter on cooling and rewarming. In the 6 patients who did not receive heparin before the induction, the platelet fall averaged 46%. One of these patients showed a pronounced hemorrhagic tendency which was controlled. This was the patient with the lowest platelet count. The 6 patients who received heparin before the induction and who underwent subsequent hypothermia had an average platelet fall of only 19%. This difference is statistically significant. No hemorrhagic tendencies were noted in this group. Before the use of small doses of heparin routinely in hypothermia, hemorrhagic tendencies were noted in 3 of 14 patients. One of these patients died within 12 hours of operation. At autopsy a large mediastinal hematoma and hemothorax were found. In 10 consecutive patients in whom small doses of heparin were used to modify the hypothermic thrombocytopenia, there was no hemorrhagic tendency or uncontrollable oozing.

In this small series of patients the use of heparin thus has minimized thrombocytopenia and has eliminated bleeding tendencies. The authors feel that heparin minimizes thrombocytopenia only if given just before cooling. It will not increase the number of circulating platelets in a patient already hypothermic. Presumably heparin acts by reducing the adhesiveness or agglutinability of platelets below a critical level.

PHYSIOLOGY

On the Placental Transfer of Vitamin C: An Experimental Study on Guinea Pigs and Human Subjects. N. Räihä. Acta physiol. scandinav. (supp. 155) 45:1-53, 1958 (In English) [Stockholm].

The process of transfer of vitamin C across the placental barrier from mother to fetus was studied in guinea pigs and in human subjects. Specimens of maternal blood, cord blood, and amniotic fluid from 9 cases of legal abortion performed at Södra Barnbördshuset in Stockholm, and from 41 normal deliveries at the Women's Clinic of the University of Helsinki, were studied. Experiments on human subjects were performed as follows. The umbilical cord was cautiously exposed by a vaginal hysterotomy made on the mother with the aid of ether anesthesia. In 3 women, initial blood samples were drawn from the umbilical vein and from the left antecubital vein, and immediately injections of 1 Gm., 1 Gm., and 1.5 Gm., respectively, of L-ascorbic acid were made into the right antecubital vein. Maternal and fetal blood samples were collected after 3, 6, and 15 minutes respectively. In 4 women, the L-ascorbic acid solution was injected into the maternal circulation some time before the exposure of and blood sampling from the umbilical cord. In vitro studies on the passage of L-ascorbic acid and dehydroascorbic acid from plasma to erythrocytes were made from adult and fetal blood in order to clarify the in vivo experiments on placental transfer. The in vitro permeability of adult and fetal human erythrocytes to dehydroascorbic acid was studied in venous blood samples from healthy adults and from the cord blood obtained during 4 normal deliveries.

The in vitro results showed that, after an addition of L-ascorbic acid to adult and fetal blood, nearly all the added vitamin remained in the plasma, and only a very slight increase of the total ascorbic acid content was found in the erythrocytes. After additions of dehydroascorbic acid to adult and fetal human blood, a marked increase of total ascorbic acid content was found in the erythrocytes, and only a slight increase was observed in the plasma. The permeation of dehydroascorbic acid into adult and fetal human erythrocytes occurred at equal rates. In the studies of blood samples of maternal and cord blood obtained in the course of legal abortions and normal deliveries, it was found that all the fetal blood samples contained more total ascorbic acid (mean, 2.01 mg. per 100 cc.) than the maternal blood (mean, 1.24 mg. per 100 cc.). Dehydroascorbic acid was distributed more equally (mean in fetal plasma, 0.40 mg. per 100 cc. and in maternal plasma, 0.38 mg. per 100 cc.) on both sides of the placenta, whereas the fetal plasma contained more L-ascorbic acid (mean, 1.06 mg. per 100 cc.) than the maternal plasma (mean, 0.40 mg. per 100 cc.). Studies relating the total ascorbic content of the amniotic fluid to that of maternal and fetal plasma showed that, when the total ascorbic acid content of the maternal plasma exceeded the mean normal value of 0.60 mg. per 100 cc., an accumulation of total ascorbic acid was found in the amniotic fluid; in contrast, when the fetal plasma showed values below the mean normal value of 1.20 mg. per 100 cc., the amniotic fluid contained an even lower total ascorbic acid concentration. Experimental studies in which L-ascorbic acid was injected into the mother, and samples of blood were taken from the umbilical cord during legal abortion, showed a slight but distinct increase of total ascorbic acid in the fetal plasma.

These findings indicate that the transfer of vitamin C across the placenta most probably occurs as dehydroascorbic acid, and that the high content of vitamin C in the fetal blood is due to an increase in the concentration of L-ascorbic acid on the fetal side of the placenta. This mechanism of transfer would make it possible for the fetus to maintain a high concentration of vitamin C.

Studies on the Renal Concentrating Mechanism: III. Effect of Heavy Exercise. L. G. Raisz, W. Y. W. Au and R. L. Scheer. J. Clin. Invest. 38:8-13 (Jan., pt. 1) 1959 [New York].

Earlier investigations had demonstrated that heavy exercise decreases urine flow, sodium excretion, glomerular filtration rate, and effective renal blood flow in man. In addition, albumin, casts, and red blood cells were often found in the urine sediment after exercise. Since the renal concentrating ability is a sensitive measure of renal impairment, the present study was undertaken to determine the effect of exercise on this function. The subjects were 6 medical students and 2 physicians. The medical students were selected for their ability to pass the "bladder emptying test," that is, they were able to void small volumes of urine so that catheterization could be avoided. The subjects took no fluid after lunch of the day prior to the experiment and at a dry supper. The heavy exercise consisted of stair running or of stepping up and down a 17-in. step every 3 seconds. Both these exercises were continued for 30 minutes. The exercises were made first without solute loading. Then they were made during solute loading after a small osmotic diuresis, which was established by the infusion of 5% mannitol in 0.36% saline solution at a rate of 3.6 to 3.9 ml. per minute for 2 hours prior to exercise. Vasopressin was added. A third series of heavy exercise was carried out after a large osmotic diuresis, which was established by the infusion of 5% mannitol in 0.36% saline at 18 to 20 ml. per minute for 90 minutes prior to exercise. Vasopressin was again added.

It was found that heavy exercise led to impairment of the concentrating ability in hydropenic normal men. This impairment was observed in experiments without solute loading and also during a small osmotic diuresis but not during a large osmotic diuresis. The effect could not be prevented by the administration of vasopressin and is, therefore, considered not to be the consequence of a decrease in endogenous antidiuretic hormone production. During a large mannitol diuresis there was no distinct change in concentrating ability or in creatinine and mannitol clearance with exercise. In all 3 groups exercise caused an abrupt decrease in total solute excretion and particularly in sodium excretion.

Motor Unit Territory in Different Human Muscles. F. Buchthal, F. Erminio and P. Rosenfalck. Acta physiol. scandinav. 45:72-87 (no. 1) 1959 (In English) [Stockholm].

Since the territory of a motor unit in human muscles is not accessible to investigation by histological techniques, the authors had previously determined the disposition of the fibers of such a unit by mapping the cross sectional distribution of its action potentials. In the human brachial biceps the fibers of a motor unit were found to be confined to a relatively small area of the total cross section of the muscle. The studies described here aimed to determine to what extent these findings apply to other muscles. In addition, the concentration of muscle fibers within the motor units in different muscles is inferred from the maximum voltage within the motor units. A multielectrode with 12 leads, inserted perpendicularly to the direction of the fibers, recorded from all fibers of a motor unit along its track. The depth of insertion was adjusted to record the potential of maximum voltage on one of the center leads. Whenever possible, insertions were made both anteroposteriorly and mediolaterally. For selection of a lead suitable as indifferent electrode, the potential was recorded between leads 1 and 12, with lead 12 as indifferent electrode. The lead which recorded the potential of highest voltage was kept in constant connection with the electromyograph.

Studies were made in 62 subjects on the following muscles: biceps brachii, deltoideus, extensor digitorum communis, opponens pollicis, rectus femoris, biceps femoris, tibialis anterior, and extensor digitorum brevis; the total number of muscles studied was 79. Potentials containing a steep deflection with a duration of less than 0.2 milliseconds (denoted as spike) were recorded on 3 to 6 leads corresponding to 4 to 10 mm. of the cross section of the muscle. The area over which the action potentials of a motor unit contained spike components was used as a gauge of the territory over which the fibers of the motor unit were distributed, since a spike signals the presence of active muscle fibers in the immediate vicinity of the lead. Thus, in the brachial biceps the muscle fibers giving rise to a spike potential of 50 microvolts are at a distance of less than 1 mm. from the recording lead. In the majority of muscles investigated, the voltage level at which spikes appeared in the action potentials was 50 to 100 microvolts. In the m. opponens pollicis and m. biceps femoris the spike level was 150 microvolts, and in the m. extensor digitorum brevis it was 200 microvolts.

The fibers of a motor unit were found to be confined to a circular area of 5 to 7 mm. in diameter for the muscles of the upper extremities and of 7 to 10 mm. in the lower extremities. Such areas allow space for the fibers of 25 motor units, each comprising 500 to 2,000 fibers. Within the same muscle, or the same type of muscle, the diameter of the motor unit territory varied by a factor of 4. The maximum voltage within the motor unit increased linearly with the territory. The different average values of maximum voltage and territory in different muscles are interpreted in terms of differences in fiber concentration and total number of fibers per motor unit.

BOOK REVIEWS

Hormones and Atherosclerosis. Proceedings of the Conference Held in Brighton, Utah, March 11-14, 1958. Edited by Gregory Pincus. Organizing Committee: Marshall E. Groover and others. Cloth. $13.50. Pp. 484, with illustrations. Academic Press, Inc., 111 Fifth Ave., New York 3, 1959.

This well-indexed volume contains the proceedings of a conference sponsored by the Endocrine Study Section of the National Institutes of Health on hormonal interaction with the atherosclerotic process. The participants, who represented several disciplines, from test-tube chemist to epidemiologist, succeeded in giving the depth of focus this important subject deserves. The spirited discussions were often more elucidating than the prepared presentations. The proceedings were concerned with (1) cholesterol metabolism and hormonal influence thereon; (2) lipogenesis and lipid transport, their hormonal control and their relationship to atherosclerosis; (3) the influence of various hormones on experimental atherosclerosis; (4) the relationships of blood lipids and the endocrine state in animals and man; and (5) certain clinical aspects related to the endocrine influence on human atherosclerosis. This volume is not a review, as the contributions often represent a report on work in progress rather than a statement of progress. The multidisciplinary approach should provide a point of entry for the student, the investigator concerned with a narrow aspect of this broad problem, and the thoughtful clinician who is not satisfied with the facile explanations that are often used to support current therapeutic approaches. In general, the reader will find no ready answers to the vexing problems posed by the conferees but rather a rich source of research leads.

Management of the Newborn. By Arthur Hawley Parmelee, M.D., Clinical Professor of Pediatrics, University of Southern California School of Medicine, Los Angeles. Second edition. Cloth. $8.50. Pp. 368, with 47 illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1959.

The new edition of this book has not changed the impression created by the excellent first edition. The chapters on streptococcic infections in the newborn, retrolental fibroplasia, hyaline membrane syndrome, and resuscitation of the newborn and infants of diabetic mothers have been rewritten and covered very well. The author has had extensive experience with newborn infants, and he covers the subject in a practical manner extremely well. It is highly recommended to obstetricians, pediatricians, and general practitioners.

Medical Department, United States Army: Surgery in World War II. Neurosurgery. Volume I. Prepared and published under direction of Major General S. B. Hays, Surgeon General, U. S. Army. Editor in chief: Colonel John Boyd Coates Jr. Editors for neurosurgery: R. Glen Spurling, M.D., and Barnes Woodhall, M.D. Associate editor: Elizabeth M. McFetridge, M.A. Office of Surgeon General, Department of Army, Washington, D. C. Cloth. $5. Pp. 466, with illustrations. Superintendent of Documents, Government Printing Office, Washington 25, D. C., 1958.

This is the first of two volumes on neurosurgery in World War II. Part 1 tells the story of the development of neurosurgical centers in the continental United States and overseas theaters of operations. Part 2 describes the management of head injuries. Outstanding advances in this field included cranioplasty with use of tantalum plates, the treatment of speech defects, and the management of posttraumatic epilepsy. The appendixes deal with (1) courses of instruction in neurosurgery, (2) extracts from the Manual of Therapy of the European Theater of Operations, (3) special history and examination forms, and (4) battle wounds of the head and brain. This should prove to be a valuable reference book for neurosurgeons, especially those in the military service. The book is well written and illustrated and is printed on paper of a high quality. There is an index.

Gynecologic Radiography. By Jean Dalsace, M.D., Chief of Sterility Clinic, Broca Hospital, University of Paris, Paris, and J. Garcia-Calderón, M.D., Radiologist, University of Paris School of Medicine. With chapter on Radiography of the Breast by Charles-M. Gros, M.D., and Robert Sigrist, M.D. Foreword by I. C. Rubin, M.D. Translated by Hans Lehfeldt, M.D. Cloth. $8. Pp. 188, with 305 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1959.

This is an excellent atlas of hysterography and hysterosalpingography. The illustrations are accompanied by clearly stated, descriptive explanatory notes. The first three chapters discuss phases of technique, incidents, and accidents to be considered in the course of hysterography and hysterosalpingography. The radiographic reproductions are of a high quality, but the use of both positive and negative reproductions is confusing. This is probably the first atlas in its field to be made available to American readers. Dr. I. C. Rubin in his foreword says: "From an abundant number of cases thus studied the authors have achieved an experience culminating in a high degree of diagnostic accuracy. This experience they have imparted to the reader of the atlas by presenting clear cut radiographs with terse descriptions implemented by the specific anatomic and path-

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

ologic findings to clarify the salient points." In discussion of techniques the authors emphasize fluoroscopic control of filling plus serial films and variable postural projections. With the current concern about cumulative radiation hazards it would seem wise to emphasize the necessity for careful selection of cases; in each instance these procedures must be fully justified. The chapter on radiography of the breast deals with techniques and limitations of interpretation. It should prove a stimulant to greater application of this diagnostic procedure. The clarity of the radiographic reproductions shows that with improved technique and experience the procedure can add much to the detection of early malignancy.

Oral Diagnosis. By Donald A. Kerr, D.D.S., M.S., Professor and Head, Department of Oral Pathology and Periodontia, University of Michigan School of Dentistry, Ann Arbor, Major M. Ash Jr., D.D.S., M.S., Assistant Professor of Dentistry (Oral Pathology and Periodontia), University of Michigan School of Dentistry, and H. Dean Millard, D.D.S., M.S., Assistant Professor of Dentistry (Oral Diagnosis), University of Michigan School of Dentistry. Cloth. $10. Pp. 419, with 212 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1959.

This textbook was written primarily for teaching at the undergraduate level and should have been called "An Introduction to Oral Diagnosis." The authors are well acquainted with the needs and level of understanding of students, the desirability of easy reading, and the necessity to present material in a logical sequence. Most texts on oral diagnosis aim at a seller's market rather than a specific goal, i. e., an attempt is made to write a book basic enough for undergraduate use and yet comprehensive enough to be used as a reference text for men in active practice. This book is unique in that it is basic enough to be of value to students without confusing them with too many details or theoretical tangents. It should be supplemented with a text on oral medicine since many signs and symptoms of systemic diseases have early manifestations in the oral cavity, but as it is not this remains a phase in which this book is exceptionally weak.

The Chemistry of Industrial Toxicology. By Hervey B. Elkins, Director, Division of Occupational Hygiene, Massachusetts Department of Labor and Industries, Boston. Second edition. Cloth. $11.50. Pp. 452, with 26 illustrations. John Wiley & Sons, Inc., 440 Fourth Ave., New York 16; Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W. C. 2, England, 1959.

In this new edition the author retains the general plan of the earlier edition and includes discussions of new developments in the field of toxicology. Hazards which are a potential menace to the health of the industrial worker are an ever-increasing problem. Attention is directed toward the more dangerous substances which include many organic compounds, especially pesticides, and some inorganic materials. The most important have been the radioactive isotopes. New analytical methods have been developed over the past decade, with particular emphasis on the analysis of body fluids. Although the medical aspects of industrial toxicology are obviously of great importance, this book seeks to outline those aspects which are the primary concern of the chemist, engineer, and factory manager.

A general treatment of industrial poisons and the more important chemical and biochemical tests and physiological methods of evaluating hazards are discussed in the first chapters. In chapters 3 through 10 various actual and potential industrial poisons are classified and their chemical and physical properties as well as harmful effects resulting from exposures in industry are discussed. The degree of toxicity is also indicated, and the maximum allowable concentration is given. In chapter 12 a number of radioactive isotopes which present a hazard to health due to the radiations emitted when they undergo radioactive decay are discussed. The rest of the book is concerned with preventive measures, industrial operations and processes, maximum allowable concentrations, air sampling devices, analytic methods and procedures which produce toxic substances, ways to minimize or eliminate their dangers, and equipment to be used in testing such poisons. The great advances in chemical technology and the increasing accumulation of toxicological data on industrial chemicals are reflected in this edition. An extensive bibliography is provided.

The Principles of Physical Education. By Jesse Feiring Williams, M.D., Sc.D. Seventh edition. Cloth. $4.50. Pp. 389, with 10 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

For nearly half a century the author has been a potent leader and a powerful influence in shaping the direction of physical education in the United States. Physical education, as he has conceived it, is education through the physical and not merely of the physical. As such it has the same objectives as all of education, with physical activities as its tools for learning. In a democracy, natural activities, sports, and games are a better expression of national philosophy than the formal gymnastics which stem from other cultures. This new edition is a reaffirmation of these principles in the light of contemporary conditions and problems.

Consistent with his philosophy of physical education the author lists its contributions to education as development of organic systems, development of neuromuscular skills, development of interest in play and recreation, and development of standards of behavior. Each of these achieves its fullest realization only with careful selection of activities, proper facilities and conditions for learning, and professionally prepared teachers and leaders. It is not enough for such leaders to be skillful perform-ers; they must have a thorough understanding of the child's growth and development, a proper background in the physiology of muscular activity, and competency in educational procedures and methods.

In discussing problems of youth fitness the author fortunately dispels the delusion that physical education might somehow cut down the rate of rejections from selective service. The causes of rejection, whether for physical or mental deficiencies, have only a remote relationship to physical education. The author might have added that the standards used by the armed services are arbitrary, subject to change, and a measure of capacity to serve rather than of health. Only a comparatively small proportion of the causes of rejection—an estimated 20%—are subject to prevention or correction by any known medical means.

After a consideration of the relationship of physical education to education and to democracy, the nature of man is discussed in terms of biological and psychological foundations. Much attention is given to curriculum construction and principles of method, guidance, and administration in physical education. Finally there is a summary of the process of appraising the results of physical education. The volume constitutes a reexamination of the role of physical education in fitting the individual to become a worthy member of society. This new edition will take its place along with its predecessors as a classic in the field.

Developmental Psychology. By Elizabeth B. Hurlock, h.D., Associate in Psychology, Graduate School, University f Pennsylvania, Philadelphia. Second edition. Cloth. $6.75. p. 645, with 131 illustrations. McGraw-Hill Book Compa- y, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E. C. 4, England; 253 Spadina Rd., Toronto 4, Canada, 1959.

This book has been revised and extended by the addition of two chapters on middle age to replace a much briefer chapter on adulthood. Working on the assumption that psychological development is a continuous process the book carries on both the traditional discussion of the developmental characteristics of infancy, childhood, and adolescence, and a discussion of available information on young adulthood, middle age, and old age, to point up the manner of psychological changes throughout the life span. The two major themes running through this book are (1) that childhood is the foundation age of life, and what the individual is and does for his remaining years depends on what forms that foundation has taken, and (2) that while physical and psychological foundations are determined by a person's hereditary endowment, how he develops that foundation will be influenced by the social and cultural patterns with which he is identified at different stages in his development.

This is a reference book rather than a popular treatise. It is detailed in its presentation of data based on experimental study. Each chapter is followed by a bibliography. Many tables and charts emphasize the point of view expressed in the text. Since the book is written in chronological form, it is easy to find the age areas in which one is interested. The index is excellent. This book could be a valuable addition to the physician's library, since it will give him an insight into social and cultural influences on the thinking of people at various ages and lead to a better understanding of why people think and react as they do to problems encountered at various stages of life.

Health Education in the Elementary School. By Carl E. Willgoose, Ed.D., Professor of Health and Physical Education, State University of New York, Oswego. Cloth. $5.25. Pp. 450, with illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

Foundations for health are laid, in large measure, before the child enters school, but the formative elementary-school years are also crucial for fostering growth and development and nurturing health. During this period the teacher's health education activities reinforce and supplement the health efforts of the home. To carry out his health-supporting role the teacher needs to know something about the characteristics of healthy children. He needs to know also how to single out children whose behavior or appearance suggests that something may be wrong with their health and how to refer them for medical investigation. Finally, and most important, he needs to know how to teach health and how to foster healthful living in his classroom.

This book attempts to provide the teacher or prospective teacher with knowledge and skills to achieve these goals. For the most part it accomplishes this purpose although at times there seems to be excessive reliance on references, a few of which might be improved on. The early chapters are devoted to the school health program in general and the health status and characteristics of the elementary school child at various developmental levels. The major portion of the volume is concerned with the teaching of health—its objectives, planning, methods, teaching techniques, and evaluation. This is as it should be, because the basic task of the school is education and the most needed emphasis in the school health program is on the teaching of health.

Long-Term Illness: Management of the Chronically Ill Patient. Edited by Michael G. Wohl, M.D., F.A.C.P. With collaboration of 79 contributing authorities. Cloth. $17. Pp. 748, with illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

This volume stresses management, first in a general and then in a specific way. The expression "long-term illness" has been substituted for chronic illness without the realization that the two terms may not be synonymous. The phrase fits in well, ologic findings to clarify the salient points." In discussion of techniques the authors emphasize fluoroscopic control of filling plus serial films and variable postural projections. With the current concern about cumulative radiation hazards it would seem wise to emphasize the necessity for careful selection of cases; in each instance these procedures must be fully justified. The chapter on radiography of the breast deals with techniques and limitations of interpretation. It should prove a stimulant to greater application of this diagnostic procedure. The clarity of the radiographic reproductions shows that with improved technique and experience the procedure can add much to the detection of early malignancy.

Oral Diagnosis. By Donald A. Kerr, D.D.S., M.S., Professor and Head, Department of Oral Pathology and Periodontia, University of Michigan School of Dentistry, Ann Arbor, Major M. Ash Jr., D.D.S., M.S., Assistant Professor of Dentistry (Oral Pathology and Periodontia), University of Michigan School of Dentistry, and H. Dean Millard, D.D.S., M.S., Assistant Professor of Dentistry (Oral Diagnosis), University of Michigan School of Dentistry. Cloth. $10. Pp. 419, with 212 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1959.

This textbook was written primarily for teaching at the undergraduate level and should have been called "An Introduction to Oral Diagnosis." The authors are well acquainted with the needs and level of understanding of students, the desirability of easy reading, and the necessity to present material in a logical sequence. Most texts on oral diagnosis aim at a seller's market rather than a specific goal, i. e., an attempt is made to write a book basic enough for undergraduate use and yet comprehensive enough to be used as a reference text for men in active practice. This book is unique in that it is basic enough to be of value to students without confusing them with too many details or theoretical tangents. It should be supplemented with a text on oral medicine since many signs and symptoms of systemic diseases have early manifestations in the oral cavity, but as it is not this remains a phase in which this book is exceptionally weak.

The Chemistry of Industrial Toxicology. By Hervey B. Elkins, Director, Division of Occupational Hygiene, Massachusetts Department of Labor and Industries, Boston. Second edition. Cloth. $11.50. Pp. 452, with 26 illustrations. John Wiley & Sons, Inc., 440 Fourth Ave., New York 16; Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W. C. 2, England, 1959.

In this new edition the author retains the general plan of the earlier edition and includes discussions of new developments in the field of toxicology. Hazards which are a potential menace to the health of the industrial worker are an ever-increasing problem. Attention is directed toward the more dangerous substances which include many organic compounds, especially pesticides, and some inorganic materials. The most important have been the radioactive isotopes. New analytical methods have been developed over the past decade, with particular emphasis on the analysis of body fluids. Although the medical aspects of industrial toxicology are obviously of great importance, this book seeks to outline those aspects which are the primary concern of the chemist, engineer, and factory manager.

A general treatment of industrial poisons and the more important chemical and biochemical tests and physiological methods of evaluating hazards are discussed in the first chapters. In chapters 3 through 10 various actual and potential industrial poisons are classified and their chemical and physical properties as well as harmful effects resulting from exposures in industry are discussed. The degree of toxicity is also indicated, and the maximum allowable concentration is given. In chapter 12 a number of radioactive isotopes which present a hazard to health due to the radiations emitted when they undergo radioactive decay are discussed. The rest of the book is concerned with preventive measures, industrial operations and processes, maximum allowable concentrations, air sampling devices, analytic methods and procedures which produce toxic substances, ways to minimize or eliminate their dangers, and equipment to be used in testing such poisons. The great advances in chemical technology and the increasing accumulation of toxicological data on industrial chemicals are reflected in this edition. An extensive bibliography is provided.

The Principles of Physical Education. By Jesse Feiring Williams, M.D., Sc.D. Seventh edition. Cloth. $4.50. Pp. 389, with 10 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

For nearly half a century the author has been a potent leader and a powerful influence in shaping the direction of physical education in the United States. Physical education, as he has conceived it, is education through the physical and not merely of the physical. As such it has the same objectives as all of education, with physical activities as its tools for learning. In a democracy, natural activities, sports, and games are a better expression of national philosophy than the formal gymnastics which stem from other cultures. This new edition is a reaffirmation of these principles in the light of contemporary conditions and problems.

Consistent with his philosophy of physical education the author lists its contributions to education as development of organic systems, development of neuromuscular skills, development of interest in play and recreation, and development of standards of behavior. Each of these achieves its fullest realization only with careful selection of activities, proper facilities and conditions for learning, and professionally prepared teachers and leaders. It is not enough for such leaders to be skillful perform-ers; they must have a thorough understanding of the child's growth and development, a proper background in the physiology of muscular activity, and competency in educational procedures and methods.

In discussing problems of youth fitness the author fortunately dispels the delusion that physical education might somehow cut down the rate of rejections from selective service. The causes of rejection, whether for physical or mental deficiencies, have only a remote relationship to physical education. The author might have added that the standards used by the armed services are arbitrary, subject to change, and a measure of capacity to serve rather than of health. Only a comparatively small proportion of the causes of rejection—an estimated 20%—are subject to prevention or correction by any known medical means.

After a consideration of the relationship of physical education to education and to democracy, the nature of man is discussed in terms of biological and psychological foundations. Much attention is given to curriculum construction and principles of method, guidance, and administration in physical education. Finally there is a summary of the process of appraising the results of physical education. The volume constitutes a reexamination of the role of physical education in fitting the individual to become a worthy member of society. This new edition will take its place along with its predecessors as a classic in the field.

Developmental Psychology. By Elizabeth B. Hurlock, Ph.D., Associate in Psychology, Graduate School, University of Pennsylvania, Philadelphia. Second edition. Cloth. $6.75. Pp. 645, with 131 illustrations. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E. C. 4, England; 253 Spadina Rd., Toronto 4, Canada, 1959.

This book has been revised and extended by the addition of two chapters on middle age to replace a much briefer chapter on adulthood. Working on the assumption that psychological development is a continuous process the book carries on both the traditional discussion of the developmental characteristics of infancy, childhood, and adolescence, and a discussion of available information on young adulthood, middle age, and old age, to point up the manner of psychological changes throughout the life span. The two major themes running through this book are (1) that childhood is the foundation age of life, and what the individual is and does for his remaining years depends on what forms that foundation has taken, and (2) that while physical and psychological foundations are determined by a person's hereditary endowment, how he develops that foundation will be influenced by the social and cultural patterns with which he is identified at different stages in his development.

This is a reference book rather than a popular treatise. It is detailed in its presentation of data based on experimental study. Each chapter is followed by a bibliography. Many tables and charts emphasize the point of view expressed in the text. Since the book is written in chronological form, it is easy to find the age areas in which one is interested. The index is excellent. This book could be a valuable addition to the physician's library, since it will give him an insight into social and cultural influences on the thinking of people at various ages and lead to a better understanding of why people think and react as they do to problems encountered at various stages of life.

Health Education in the Elementary School. By Carl E. Willgoose, Ed.D., Professor of Health and Physical Education, State University of New York, Oswego. Cloth. $5.25. Pp. 450, with illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

Foundations for health are laid, in large measure, before the child enters school, but the formative elementary-school years are also crucial for fostering growth and development and nurturing health. During this period the teacher's health education activities reinforce and supplement the health efforts of the home. To carry out his health-supporting role the teacher needs to know something about the characteristics of healthy children. He needs to know also how to single out children whose behavior or appearance suggests that something may be wrong with their health and how to refer them for medical investigation. Finally, and most important, he needs to know how to teach health and how to foster healthful living in his classroom.

This book attempts to provide the teacher or prospective teacher with knowledge and skills to achieve these goals. For the most part it accomplishes this purpose although at times there seems to be excessive reliance on references, a few of which might be improved on. The early chapters are devoted to the school health program in general and the health status and characteristics of the elementary school child at various developmental levels. The major portion of the volume is concerned with the teaching of health—its objectives, planning, methods, teaching techniques, and evaluation. This is as it should be, because the basic task of the school is education and the most needed emphasis in the school health program is on the teaching of health.

Long-Term Illness: Management of the Chronically Ill Patient. Edited by Michael G. Wohl, M.D., F.A.C.P. With collaboration of 79 contributing authorities. Cloth. $17. Pp. 748, with illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W. C. 2, England, 1959.

This volume stresses management, first in a general and then in a specific way. The expression "long-term illness" has been substituted for chronic illness without the realization that the two terms may not be synonymous. The phrase fits in well, however, with the modern concept of hospitalization which has the patients flowing into the sections of the hospital which can best serve their needs. The book is well organized and presents timely information for the practitioner who is still a student. This is especially true in the discussion of the psychological problem of and nursing procedures in the care of the chronically ill. The considerations taken up in this section are basic to the management of the specific diseases discussed in part two. In this part the management of most long-term illnesses is discussed specifically. In some areas of this section the treatment suggested seems to proceed almost too quickly to the more severe and complicated procedures. More recent graduates may not realize that some chronic states may best be treated by studied neglect, at least for a time.

Handbuch der Orthopädie. In vier Bänden. Herausgegeben von Prof. Dr. G. Hohmann, Prof. Dr. M. Hackenbroch, Direktor der Orthopädischen Universitätsklinik Köln, und Prof. Dr. K. Lindemann, Direktor der Orthopädischen Universitätsklinik Heidelberg-Schlierbach. **Band II: Spezielle Orthopädie: Rumpf (Wirbelsäule und Becken).** Bearbeitet von R. Bernbeck et al. Cloth. 174 marks; $41.45. Pp. 1136, with 846 illustrations. Georg Thieme Verlag, Herdweg 63, (14a) Stuttgart, West Germany; [Intercontinental Medical Book Corporation, 381 Fourth Ave., New York 16], 1958.

This second volume in a series of four is devoted to surgery of the spinal column and pelvis. The book opens with a historical review of the subjects under discussion, and it is heartening to note that the editors are thoroughly acquainted with the surgical literature of the world. The chapters on scoliosis and tuberculosis are outstanding, as are the chapters on trauma and neurological disturbances due to spinal diseases. There is a wealth of information in this part of the work, and the author of each chapter is highly competent. The chapter on scoliosis by Lindemann contains practically everything one needs to know about the history, pathology, and treatment of this condition. The treatment is highlighted by the work of such North American surgeons as Risser and Cobb. It is stated, "Early surgery is indicated in scoliosis, but the prognosis is unfavorable." To this should be added that it is most difficult to predict the outcome of operation in these instances.

The chapter on tuberculosis suggests differences in the treatment as carried out in Germany and in the United States—spinal fusion in childhood is considered contraindicated by most German surgeons, while it is recommended in the United States. The use of a posterior plaster shell in lordosis is emphasized in Germany, while in the United States a vertebral collapse is considered essential in the early healing of the lesion. A great deal of effort has been expended by the authors to bring this work up to date. It is thorough and authoritative. Every orthopedic surgeon should have this highly recommended work in his library.

Radioactive Isotopes in Clinical Practice. By Edith H. Quimby, Sc.D., Professor of Radiology (Physics), College of Physicians and Surgeons, Columbia University, New York, Sergei Feitelberg, M.D., Associate Clinical Professor of Radiology, College of Physicians and Surgeons, Columbia University, and Solomon Silver, M.D., Associate Clinical Professor of Medicine, College of Physicians and Surgeons, Columbia University. Cloth. $10. Pp. 451, with 97 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1958.

This book is an introduction to the relatively new field of nuclear medicine. During the past five years the authors have conducted a comprehensive course in the clinical uses of radioactive isotopes. It is from the experience gained in the presentation of this course that this book has been written. The first section, Basic Physics, is written by Dr. Quimby. The basic materials of atomic and nuclear physics, interaction of radiation and matter, radiation dosimetry, radiation hazards, and related subjects are presented in a succinct and integrated manner. Historical accounts of advances in the field, which the reader should find interesting and informative, are interspersed. The section by Dr. Feitelberg deals with instrumentation and laboratory methods. Radiation detectors and measuring instruments are discussed, with respect to principles of operation as well as practical use. Chapters on the quantitative measurement of isotopes in vivo, the time factor in physiological processes, measurement of the distribution of isotopes within the body, and autoradiography are included. The section concludes with chapters on the use of radiation detectors for health protection and laboratory design. The subject material is well covered, although the reader may find the author's style a bit monotonous.

The final section, Clinical Application, is written by Dr. Silver. There are many uses for radioisotopes in many fields of clinical practice. The most widely used is radioiodine in the study of thyroid function and the treatment of certain disorders of the thyroid. The author devotes much of his section to these subjects, which are discussed in a clear and logical manner. Great emphasis is placed on the physiological mechanisms involved and the various ways the radioiodine tracer may be used to elucidate these mechanisms. A valuable discussion of pitfalls in the interpretation of such tests is included. The portion covering treatment with radioiodine is equally well presented. The remainder of this section is disappointing; various commonly used tests are mentioned but no critical evaluation of their usefulness, clinical indications, or underlying physiological basis is provided. This book should be useful to persons interested in learning the various uses of radioisotopes in medicine and the physics and instrumentation involved. Persons teaching this subject at both undergraduate and postgraduate levels should find it a useful textbook and an excellent example of a course presentation that has proved successful.

QUESTIONS AND ANSWERS

PROGRESSIVE MUSCULAR ATROPHY

To the Editor:—*An 18-month-old girl was given the diagnosis of progressive muscular atrophy in October, 1958. Is there a definite difference between a hereditary and an acquired type of this disease? If so, how can this be determined? Is there a likelihood of a similar disease in any future children that this family might have? What is the earliest age at which this disease can be diagnosed? Can a 3½-year-old sibling in the same family be considered free of this disease? What is the usual life expectancy after this diagnosis has been made?*

Lloyd C. McCaskill, M.D., Maxton, N. C.

Answer.—It is probable, if the diagnosis of progressive muscular atrophy has been made in an 18-month-old child, that this patient has the Werdnig-Hoffmann type. This usually comes on during the first year of life and is progressive. It is believed to be hereditary, although sporadic cases have been described. Clinically, there is no differentiation between the hereditary and sporadic varieties. It is generally agreed by clinicians that there is a likelihood of similar disease in future children of such a family. The disease is rarely diagnosed prior to the age of 6 months. If a sibling has reached the age of 3½ years without being affected, it may be safely assumed that the child will not develop this type of muscular atrophy. The usual course of the disease is from one to three years. It is unusual for such patients to live to the age of 5 years.

BRADYCARDIA

To the Editor:—*What treatment should be given a patient who has sinus bradycardia but no physical, electrocardiographic, or roentgenographic evidence of heart disease, arteriosclerosis, or jaundice? He may have a mild hypothyroidism. His heart rate varies between 40 and 58 beats per minute. He has had a spell of faintness with weakness and sweating but no evidence of hypoglycemia. Thyroid extract, ephedrine, and amphetamine have been tried without success.*

R. J. Kent, M.D., Savannah, N. Y.

Answer.—Sinus bradycardia with a rate between 50 and 60 per minute is common in normal persons, and rates as low as 36 per minute may be found in healthy persons without symptoms of any kind. Occasionally these slow rates are accompanied by dizziness or syncope, as in the patient described. In the absence of heart disease and when other causes of bradycardia, such as myxedema, sensitivity of the carotid sinus, increased intracranial pressure, and jaundice, are excluded, reassurance is usually all that is needed. If dizziness or syncope recur without other apparent reason, 0.3 or 0.4 mg. of atropine three or four times daily, after meals, may be given as a therapeutic and prophylactic measure.

FOOTBALL AFTER SPLENECTOMY

To the Editor:—*A 21-year-old man who had a splenectomy two years ago for an injury now wishes to play football. At present, physical and neurological examinations are within normal limits except for a blood pressure of 155/90 mm. Hg in the upper extremities and 170/100 mm. Hg in the lower extremities. He is asymptomatic, and his weight is normal for his age and height. Urinalysis, blood cell count, sedimentation rate, bleeding and clotting time, platelet count, clot retraction, blood urea nitrogen level, and other findings are within normal limits. An intravenous pyelogram, roentgenogram of the chest, and electrocardiogram reveal no abnormalities. Is splenectomy a contraindication for playing football?*

Waldo Greespan, M.D., Hackensack, N. J.

Answer.—Splenectomy in normal animals does not produce any measurable change, except for the immediate effects associated with the operation. The spleen does serve as a reservoir for erythrocytes which may be added to the general circulation after rapid blood loss or similar emergencies. After the loss of the spleen, other capillary beds may hold more red blood cells for this purpose. Bollman and co-workers (*Surgery* 4:881, 1938) found that normal dogs added red blood cells from the spleen to the general circulation when anesthetized with ether. Splenectomized dogs did not add so much, and a somewhat greater reduction of total blood volume occurred in the splenectomized animals than in the normal dogs receiving ether. Many human beings have maintained active lives after splenectomy for traumatic or medical reasons. This consultant knows of no reports tending to show any deleterious sequelae that could be attributed to the absence of the spleen. A football injury should not be more complicated because of the absence of the spleen.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

MULTIPLE SCLEROSIS BOOK

To the Editor:—*A patient with multiple sclerosis has brought to his physician's attention the book by Jonez and Gross, "My Fight to Conquer Multiple Sclerosis" (New York, Julian Messner, Inc., 1952). Is Jonez' technique still being used at his multiple sclerosis clinic at St. Josephs Hospital, Tacoma, Wash.?*

Jacob Melnick, M.D., Brooklyn, N. Y.

Answer.—The treatment of multiple sclerosis by Jonez was essentially an application of the principles of physical medicine to the disease. There is no doubt that this form of treatment resulted in improvement in the physical status and the ability of the patient to perform, particularly in static cases. The treatment has no effect on the underlying cause of the disease, nor does it have any effect on the ultimate progress. It is believed that the techniques advised by Jonez are still being used at the multiple sclerosis clinic named.

WEIGHT OF TWINS

To the Editor:—*Twin boys weighed at birth 4,252.4 Gm. (9 lb. 6 oz.) and 3,742 Gm. (8 lb. 4 oz.) respectively. The mother was a multipara, and delivery was normal. What is the record combined weight for twins?*

Lucius D. Hill Jr., M.D., San Antonio, Texas.

Answer.—The birth of living twins with a combined weight of 8,000 Gm. or more is rare. Larger babies have been reported. Holzapfel in 1935 reported twin boys weighing 4,670 Gm. (10 lb. 5 oz.) and 4,510 Gm. (9 lb. 15 oz.). Guttmacher noted that the heaviest pair of twins in 346 sets weighed 7,680 Gm. (17 lb.). Mathieu (*Northwest Med.* 37:137, 1938) reviewed the literature on large twins rather completely and found three reports of twins with combined weights of 7,000 Gm. (15 lb. 6 oz.) or more. He notes that there are isolated reports of much larger twins in the older literature, but the authenticity of some of these may be questioned.

PERINEVIC VITILIGO

To the Editor:—*What is the treatment and the prognosis if untreated in perinevic vitiligo?*

Seymour L. Hanfling, M.D., East Orange, N. J.

Answer.—Perinevic vitiligo (halo nevus) is an innocuous and benign condition consisting of a central area of pigmentation surrounded by a depigmented area of vitiligo. The central hyperpigmentation may be a nevus or a freckle. The surrounding depigmentation is similar to the vitiligo seen elsewhere in the skin of a vitiliginous process. No treatment is necessary, but, if decided on, it consists of surgical excision. Excision should encompass the central pigmentation and, where feasible, include the area of surrounding depigmentation. If the lesion is large the entire area cannot be removed in the excision.

CARCINOMA OF THE PANCREAS

To the Editor:—*Is any form of chemotherapy or radiation therapy effective against carcinoma of the pancreas? A young man who was explored surgically was found to have an inoperable carcinoma of the pancreas.*

John D. Lynch, M.D., Manitowoc, Wis.

Answer.—There is no effective treatment for inoperable carcinoma of the pancreas. Harper, of the University of Chicago, has devised a method of irradiating the pancreas with radioisotopes placed about the organ by means of long polyethylene tubes woven around the pancreas at the time of the exploratory operation. While there have been no cures by this method, there has been some worthwhile palliation. He has written several papers describing his technique.

RECURRENT JAUNDICE

To the Editor:—*With regard to the patient described in the question on recurrent jaundice, which appeared in* The Journal, *Feb. 14, 1959, page 778, I believe that the diagnosis of obstructive jaundice was too lightly dismissed. The history revealed pain in the right upper abdominal quadrant. The direct bilirubin level was elevated. The result of the test for liver disease was essentially normal. I believe this patient had a partial obstruction of the common bile duct with a ball-valve effect. The gallstone obstruction might come from bilirubin calculi, secondary to a hemolytic jaundice, but obstruction was present nevertheless. Cholecystograms are diagnostic in about 85% of the cases, and any internist can recall several patients with a normal cholecystogram and stones found at operation. An intravenous cholangiogram should be done on this patient, but even if this should prove negative an exploration should be performed.*

Louis Pelner, M.D.
1352 Carroll St.
Brooklyn 13, N. Y.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*This is a difficult problem and one that cannot be categorically answered on the basis of the stated evidence. It is true that pain or distress was present in the right upper quadrant, but this is not an uncommon complaint in patients with recurrent hepatitis. It is also true that the direct bilirubin level was elevated on one occasion, but it was normal on the other. Again, however, this is consistent with recurrent hepatitis. This consultant believes that the critical findings in this patient were those of splenomegaly. This is not seen in patients with obstructive jaundice unless the obstruction has been present long enough to produce moderately se-*

vere liver damage. Finally, the absence of an elevated alkaline phosphatase level speaks strongly against obstruction. On the other hand, it is not thought that one can be certain of the diagnosis in this case. The findings were confusing and did not fit any definite diagnosis in a clear-cut way. An intravenous cholangiogram might provide evidence of obstruction. If further study and liver biopsy fail to establish a diagnosis, then certainly surgical exploration is justified. One could argue with merit that surgical exploration with liver biopsy and probably with common duct exploration is justifiable now. Even if obstruction seems to be unlikely, it must be remembered that this is a condition that can be corrected and that, if it is allowed to persist, permanent liver damage will ultimately result.

CELIAC DISEASE SYNDROME

To the Editor:—*In regard to the question on celiac disease syndrome, which appeared in* The Journal, *Jan. 10, 1959, page 202, the consultant's reply seemed incomplete. It must be admitted that the question did not supply enough data for adequate appraisal of the situation, but I believe the inquirer (whose patient was a 2-year-old child with "celiac disease syndrome," nasal discharge, and frequent infections) should have been advised to consider the possibility of agammaglobulinemia. Agammaglobulinemia is a sufficiently new disease for surprises still to occur, and one must keep an open mind in thinking about it. Frequent infection in a young child (usually male) is the most common presenting complaint. Intestinal disturbances having much in common with sprue or celiac disease have been noted in many adults with acquired agammaglobulinemia and yet may be found in children. There is no need to dwell on the importance of thinking of a rare disease for which specific diagnostic and therapeutic measures are available. If these are not available to the inquiring physician in this case, appropriate tests could be performed if he wishes to submit a sample of serum to the National Heart Institute, Bethesda 14, Md.*

Robert S. Gordon Jr., M.D.
3915 Prospect St.
Kensington, Md.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*The above criticism seems to be quite proper. Congenital agammaglobulinemia, a rare, recently described syndrome, should have been included in the differential diagnosis. It is diagnosed by testing the patient's serum for the gamma globulin level. These patients have a complete inability to synthesize gamma globulin. Soon after the age of 6 months they have severe and repeated bacterial infections, because their maternal supply of gamma globulin becomes exhausted. In acquired hypogammaglobulinemia, the syndrome may result from repeated severe and prolonged infections that are not necessarily, per se, the cause of the syndrome. Many well-equipped laboratories estimate the gamma globulin level; 10 ml. of freshly drawn blood or 5 ml. of serum is needed. These patients require repeated intramuscular maintenance doses of gamma globulin (100 to 150 ml. per kilogram of body weight every two to four weeks).*

CARBON MONOXIDE AND NERVE DEAFNESS

To the Editor:—*A question concerning a possible relationship between carbon monoxide poisoning and nerve deafness appeared in* The Journal, *Jan. 3, 1959, page 163. In his answer, the consultant stated, "Practically all toxicologists believe there is no such condition as the expression 'chronic carbon monoxide poisoning' would imply." It would be appreciated if the consultant would reconcile this statement with that of Katz: "Our experience during the past three years indicates that illness arising out of chronic exposure to CO is by no means rare"* (Canad. M. A. J. *78:182, 1958). Katz reviews, in this report, 41 cases of chronic carbon monoxide poisoning. A pamphlet entitled "Carbon Monoxide" (Occupational Health Division, Department of National Health and Welfare, Ottawa, Canada) contains a brief description of an entity designated as "chronic poisoning." It is important to arrive at a generally accepted understanding in this matter, because apparently some compensation boards will now accept claims for illness arising out of exposure to carbon monoxide on the job.*

George X. Trimble, M.D.
Seaside Memorial Hospital
Long Beach 13, Calif.

To the Editor:—*In the Jan. 3, 1959, issue of* The Journal, *page 163, there appears an inquiry concerning carbon monoxide and nerve deafness. The consultant correctly stated that he could find no evidence in the American literature to suggest that carbon monoxide produced nerve deafness. His final statement that "it is logical to assume that there exists no relationship between nerve deafness and carbon monoxide exposure" is perhaps not entirely justified in view of the extensive literature, particularly from Scandinavia. A monograph entitled "Hearing Deficiencies Caused by Carbon Monoxide," by Dr. J. S. Lumio, was published in Helsinki, Finland, in 1948 (for an abbreviated version, see* Acta oto-laryng., *supp. 71, p. 1, 1948). There also is an extensive monograph on chronic carbon monoxide poisoning by Dr. Aage Grut of Denmark, in which various clinical conditions, including im-*

paired hearing, are described. Having personally visited the laboratories in which much of this work was done, I have no reason to believe that the reliability of the reports is on a lower level than that covering work done in leading American institutions. I believe that the existence of permanent injury due to chronic carbon monoxide exposure can no longer be denied, even though experience in the United States has not revealed any such cases.

Leonard J. Goldwater, M.D.
600 W. 168th St.
New York 32.

The above comments were referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*Although carbon monoxide is the oldest known noxious gas, certain aspects of its toxicity remain controversial. It is difficult to understand why this should be unless certain factors are evaluated. Medical literature is prone to perpetuate unfounded as well as substantiated opinion. The more hoary the syndrome, the more prolific is the literature related to it—a situation which presents difficulties when one attempts to differentiate statements that possess authority from those that lack authority. The abstracting system, widely in vogue, will summarize an article and pass it on to the reader even though the abstractor may know little about the subject or fail to recognize errors in the original manuscript or text. This observation most certainly applies to chronic carbon monoxide intoxication. Then, too, carbon monoxide gas is ubiquitous. Therefore, observations as to its toxicity have been recorded in many languages under varying circumstances, a situation which gives rise to a diversity of opinion. Too seldom is it appreciated that the incomplete combustion of carbon may, and often does, give rise to other hydrocarbon gases.*

The preceding paragraph serves to preface the following discussion, which is confined to a consideration of that condition often inappropriately termed "chronic carbon monoxide poisoning." No consideration will be given to the multiple, bizarre effects resulting from acute carbon monoxide anoxia. The controversy over the effects of repeated exposure to minimal concentrations of this gas arise at frequent intervals and must, at such times, be considered in the light of existing knowledge. Some months ago the editor of The Journal *received this question: "Under what circumstance does carbon monoxide poisoning result in nerve deafness?" The answer stated, in essence, that practically all toxicologists believe there is no such condition as the expression chronic carbon monoxide poisoning would imply and that no evidence that exposure to carbon monoxide produced nerve deafness could be found in the American literature.*

*The observations of Lumio referred to in the comment were made on the people of northern Finland who, during the World War II years, were deprived of liquid fuels. Their recourse was to carbon monoxide generators with charcoal used as the basic fuel. From such generators would come carbon monoxide and, in addition, could come certain nitrogenous compounds, as well as other hydrocarbons. Lumio's work dealt at some length with dizziness, giddiness, headache, and aspects of vestibular and cochlear dysfunction. In a more recent article (*Arch. Gewerbepath. u. Gewerbehyg. **13:***139; 1954), he has concluded that findings in such situations are not completely diagnostic. Further reference could be made to the monograph of Dr. Aage Grut and to one or two others to be found in the foreign literature. It is not the intent of this consultant to discredit their observations. It can only be reiterated that a diversity of opinion arises out of varying circumstances which are not fully comprehended without first-hand observation. For several years, a Committee of the Council on Industrial Health of the American Medical Association and the Committee on the Conservation of Hearing Loss of the American Academy of Ophthalmology and Otolaryngology have studied hearing loss among the industrial workers in America. Admittedly their chief concern has been the noise problem, yet a hearing loss due to constant exposure to carbon monoxide has not been called to their attention.*

Carbon monoxide is a by-product of innumerable processes in industry and has been since the beginning of American industry. If there were an incidence of hearing loss due to exposure to this gas, it would not have escaped the attention of the industrial toxicologists or hygienists. The title of the article by Katz, "Carbon Monoxide Asphyxia, a Common Clinical Entity," is somewhat misleading, in that the author presented only one case, that of a patient with acute intoxication. The rest of the paper dealt with minute, daily exposures. Much misunderstanding arises out of the word "chronic" as applied to carbon monoxide exposure. A chronic disease is "a disease of long duration" (Webster). No toxicologist would deny that daily exposure to minimal amounts of carbon monoxide may produce temporary headache, dizziness, fatigue, or even drowsiness, along with other minor disturbances. These are not caused by permanent pathological changes and clear up after removal from exposure. There is adequate testimony in the literature that carbon monoxide is not cumulative.

SENATORS URGED TO BOOST MEDICAL RESEARCH FUNDS FURTHER

Scores of witnesses appeared before a Senate Appropriations subcommittee to advocate sharply increased spending on federal medical research programs.

The subcommittee, headed by Sen. Lister Hill (D., Ala.), is considering a House-passed measure granting the National Institutes of Health 344 million dollars for the fiscal year starting July 1, an increase of 50 million dollars over the administration request.

Although Arthur S. Flemming, Secretary of Health, Education and Welfare, said the Senate should try to keep spending for the NIH in check, most of the witnesses urged even higher outlays than voted by the House.

Sen. Hill said that at least 110 million dollars should be spent on cancer research alone in memory of the late John Foster Dulles. The House approved 83 million dollars and President Eisenhower recommended 75 million dollars.

Sen. Richard M. Neuberger (D., Ore.) proposed a long-range 500-million-dollar cancer research program, more than the 344 million dollars the House approved for all of the NIH's operations next fiscal year.

Dr. Isadore S. Ravdin, chief consultant physician to President Eisenhower during his ileitis illness, and Dr. Sidney Farber, of the Harvard Medical School, both labeled the administration's cancer research budget inadequate. Dr. Farber said at least 110 million dollars is needed to exploit gains already made.

Dr. Walter Bauer, medical services chief of Massachusetts General Hospital, said the Senate should appropriate 134 million dollars more for the NIH than the House. He told the subcommittee it was "foolish" for the administration to talk about a balanced budget when an unbalanced one "would help make Americans healthy and strong."

CITIZENS APPOINTED TO ADVISORY COMMITTEE FOR AGING CONFERENCE

President Eisenhower named 130 citizens, including 13 physicians, to serve on the National Advisory Committee for the White House Conference on the Aging. The conference, to be held in January, 1961, will consider all problems of the nation's aging population—financial, medical, recreational, and from the aspects of social and civic participation and housing.

The advisory committee represents all segments of the population—the medical and legal professions, business, labor, agriculture, and public and private organizations concerned with the aging. Head of the group is Robert W. Kean of New Jersey, who served for many years as a Republican member of the House of Representatives.

Arthur S. Flemming, Secretary of Health, Education and Welfare, declared that the conference will be "one of the most important and significant undertakings of our society today because it is concerned with a most vital area of American life.

"A total national effort will be required to assure the success of our mission to make the added years of life for our fellow citizens more comfortable, useful and meaningful," he said.

The 13 physicians named to the advisory committee are:

Dr. Edward L. Bortz of Cynwyd, Pa., a past-president of the American Medical Association and now president of the medical staff at Lankenau Hospital in Philadelphia.

Dr. Berwyn F. Mattison, Tarrytown, N. Y., executive secretary of the American Public Health Association.

Dr. Howard A. Rusk, Scarsdale, N. Y., director of the Institute of Rehabilitation and Physical Medicine, Bellevue Medical Center, New York, and chairman of the Department of Physical Medicine and Rehabilitation at the New York University College of Medicine.

Dr. Ewald W. Busse, chairman of the Department of Psychiatry, Duke University Medical School, Durham, N. C.

Dr. Will E. Neal, Huntington, W. Va., Republican congressman for two terms.

Dr. Edwin L. Crosby, Winnetka, Ill., director of the American Hospital Association, Chicago.

Dr. Walter U. Kennedy, Newcastle, Ind., president of the Henry County (Ind.) Welfare Board.

Dr. Frederick C. Swartz, East Lansing, Mich., Chairman of the Committee on Aging of the AMA.

Dr. William B. Kountz, St. Louis, assistant professor of Clinical Medicine at the Washington University (St. Louis) School of Medicine.

Dr. Leonard W. Larson, Bismarck, N. D., Chairman of the Board of Trustees of the AMA.

Dr. Hayden H. Donahue, Oklahoma City, director of the Oklahoma Department of Mental Health.

Dr. Norman R. Sloan, Honolulu, chief of the Bureau of Geriatrics of the Hawaii Department of Health.

Dr. Cecil G. Sheps, general director of the Beth Israel Hospital in Boston and clinical professor in preventive medicine at Harvard Medical School.

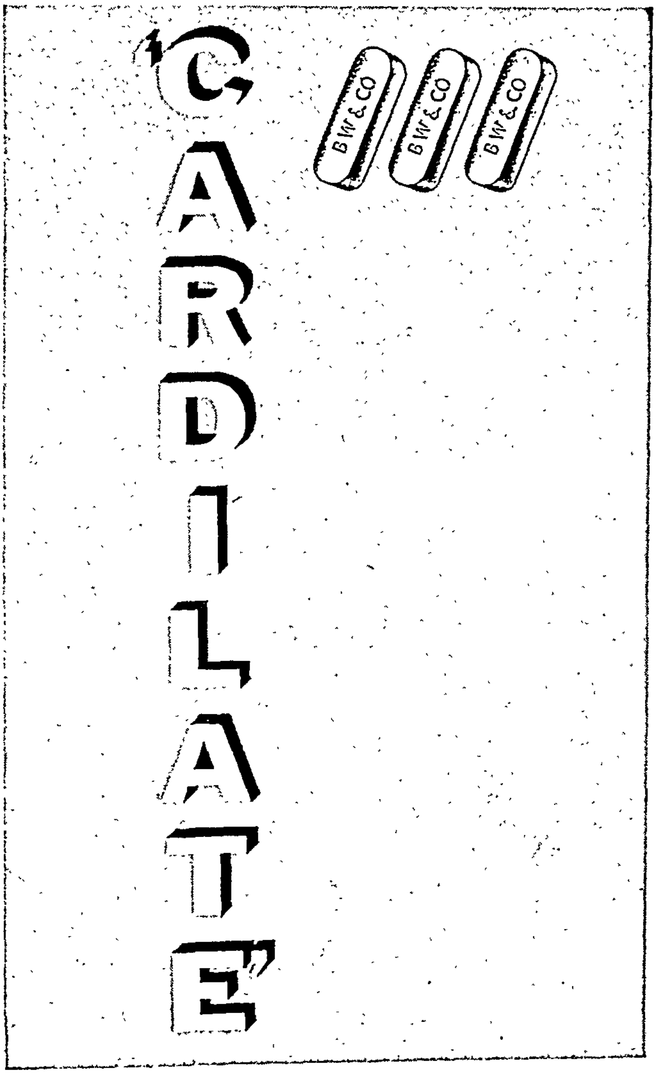
'CARDILATE' sublingual tablets for angina pectoris

"Nitroglycerin and erythrol tetranitrate when administered sublingually are among the most effective of all prophylactic agents available for the treatment of patients with angina pectoris. The comparatively prolonged duration of action of erythrol tetranitrate makes it especially valuable for clinical use."

Riseman, J. E. F., *et al.*: Circulation *17*:22, 1958

'Cardilate' brand Erythrol Tetranitrate
Sublingual Tablets 15 mg., scored.

BURROUGHS WELLCOME & CO. (U.S.A.) INC.
Tuckahoe, N. Y.



Other prominent persons appointed include G. Warfield Hobbs, chairman of the National Committee on Aging of the National Social Welfare Assembly; Charles I. Schottland, former Social Security Administrator; Thomas C. Desmond, former chairman of the New York State Joint Legislative Committee on Problems of the Aging; Nelson H. Cruikshank, director of the AFL-CIO Department of Social Security; Gen. Alfred M. Gruenther, president of the American Red Cross, Karl Schlotterbeck, director of the Economic Security Program of the U. S. Chamber of Commerce; Mrs. Florence L. Baltz, president of the American Nursing Home Association, and Mrs. Buddy Rogers, (Mary Pickford), former movie star.

HOUSE APPROVES MEDICARE FUNDS

The House voted to give the administration the full $88,800,000 it sought to run the Defense Department's Medicare program in the fiscal year starting July 1. Although the total is about 5 million dollars less than the estimated $94,400,000 the program will cost this fiscal year, it is considerably more than the suggested 60-million-dollar level advanced by the House Appropriations Committee last year.

Medicare authorizes treatment in civilian hospitals of qualified dependents of members of the Armed Forces.

The Appropriations Committee, in approving the $88,800,000 as part of the over-all 38.8-billion-dollar defense budget, said in a report that the Defense Department "is to be commended for its response to the intent of Congress in the program." The group noted that it slashed money for Medicare last year, causing restrictions that were put into effect too late to have a major impact on spending this fiscal year.

The praise came in contrast to the criticism the same committee levelled at the department only a few months ago. Acting on an emergency appropriations bill the lawmakers said they were "concerned with the high costs of care for military personnel and their dependents in civilian hospitals and the high fees allowed in the program." There was no mention of fees in the latest report.

The committee again urged that dependents of military personnel use military hospitals whenever possible rather than private hospitals. "There are no doubt some shortcomings in the service provided by military hospitals, but the committee does not feel that the problem can be solved by deserting the military facilities and adding to the already heavy burden on civilian hospital facilities."

There was some speculation earlier this year that Congress might make deep cuts in the Medicare program, but the House vote apparently ruled this out.

The Appropriations Committee declared that the Defense Department is studying Medicare, "and it is hoped that steps can ultimately be taken which may further reduce the costs of the dependents' medical care program without depriving the dependents of the benefits which the Congress wishes them to have."

ARTHRITIS DRUG STUDY ANNOUNCED

The Public Health Service and nine clinical centers across the country plan to start a study of 200 arthritis and rheumatism victims next fall to determine the value of drugs in combating the ailments. The study will be financed by PHS and the Arthritis and Rheumatism Foundation at an estimated cost of $35,000 to $50,000 a year.

Dr. Joseph J. Bunim of the National Institutes of Health, President of the American Rheumatism Association, said objective tests of various drugs used in treatment of these diseases are urgently needed now as the first step in a broader study of the ailments.

In addition to the PHS National Institute of Arthritis and Metabolic Diseases the following institutions will take part in the program: Columbia University, Massachusetts General Hospital, University of Miami (Fla.), University of Pennsylvania, University of Colorado, University of California (Los Angeles and San Francisco), University of Illinois, and University of Michigan.

SENATE SESSIONS SLATED ON AGING PROBLEMS

A special Senate Subcommittee, set up to investigate the problems of the elderly, charted panel discussions starting June 16 as the groundwork for later hearings across the nation.

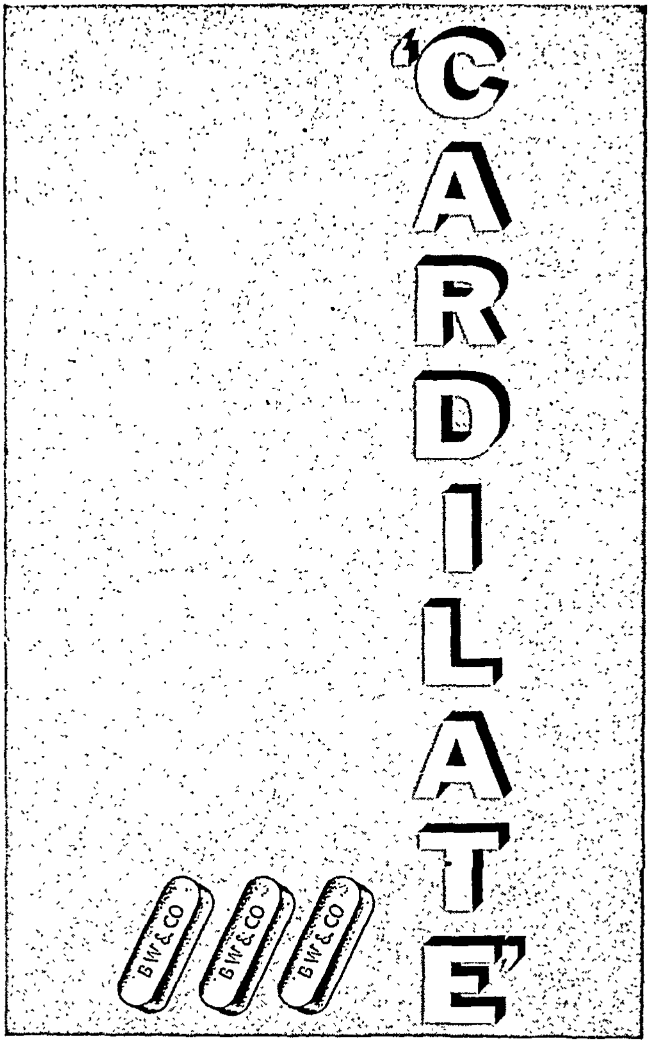
Experts on various phases of the problem of aging were summoned to public panel discussions for three days. Sidney Spector, staff chief of the Labor and Public Welfare Subcommittee that is headed by Sen. Pat McNamara (D., Mich.), said the sessions are designed to acquaint members of the subcommittee with the broad scope of the problems involved. The discussions will center on income maintenance, financing medical and hospital care, employment, and housing.

Among other panelists scheduled to participate are Dr. Howard A. Rusk of New York University College of Medicine and Bellevue Medical Center; Dr. Frederick Swartz, chairman of the American Medical Association Committee on Aging, and Nelson Cruikshank, director of the AFL-CIO Department of Social Security.

MISCELLANY

HEW Secretary Arthur S. Flemming formally sent to Congress a proposed bill to insure safe use of color additives in foods, drugs, and cosmetics. The measure would authorize tolerances, limitations, and other conditions of use, and provide for official testing and certification. At present, the government must ban any coal-tar dyes if their use in large quantities is harmful, even though small quantities would be safe.

The Atomic Energy Commission cut the price of carbon-14, a reactor-produced radioisotope widely used in biological and medical research, from between $22 and $28 a millicurie to $13 a millicurie. Price reductions were also made for the less widely-used radioisotopes chlorine-36, gold-198, and iron-59.



'CARDILATE'

sublingual tablets for angina pectoris

Sublingual administration obviates inactivation of nitrites in gastrointestinal tract.

Most closely approximates nitroglycerin in frequency and degree of effectiveness.

'Cardilate' brand Erythrol Tetranitrate
Sublingual Tablets 15 mg., scored.
